

Generalised Reactive Processes in Isabelle/UTP

Simon Foster

Samuel Canham

August 9, 2019

Abstract

Hoare and He’s UTP theory of reactive processes provides a unifying foundation for the semantics of process calculi and reactive programming. A reactive process is a form of UTP relation which can refer to both state variables and also a trace history of events. In their original presentation, a trace was modelled solely by a discrete sequence of events. Here, we generalise the trace model using “trace algebra”, which characterises traces abstractly using cancellative monoids, and thus enables application of the theory to a wider family of computational models, including hybrid computation. We recast the reactive healthiness conditions in this setting, and prove all the associated distributivity laws. We tackle parallel composition of reactive processes using the “parallel-by-merge” scheme from UTP. We also identify the associated theory of “reactive relations”, and use it to define generic reactive laws, a Hoare logic, and a weakest precondition calculus.

1 Trace Algebras

```

theory Trace-Algebra
  imports
    UTP-Toolkit.List-Extra
    UTP-Toolkit.Positive
begin

```

Trace algebras provide a useful way in the UTP of characterising different notions of trace history. They can characterise notions as diverse as discrete event sequences and piecewise continuous functions, as employed by hybrid systems. For more information, please see our journal publication [4].

1.1 Ordered Semigroups

```

class ordered-semigroup = semigroup-add + order +
  assumes add-left-mono:  $a \leq b \implies c + a \leq c + b$ 
  and add-right-mono:  $a \leq b \implies a + c \leq b + c$ 
begin

```

```

lemma add-mono:
   $a \leq b \implies c \leq d \implies a + c \leq b + d$ 
  using local.add-left-mono local.add-right-mono local.order.trans by blast

end

```

1.2 Monoid Subclasses

```

class left-cancel-monoid = monoid-add +
  assumes add-left-imp-eq:  $a + b = a + c \implies b = c$ 

class right-cancel-monoid = monoid-add +
  assumes add-right-imp-eq:  $b + a = c + a \implies b = c$ 

```

Positive Monoids

```

class monoid-pos = monoid-add +
  assumes zero-sum-left:  $a + b = 0 \implies a = 0$ 
begin

lemma zero-sum-right:  $a + b = 0 \implies b = 0$ 
  by (metis local.add-0-left local.zero-sum-left)

lemma zero-sum:  $a + b = 0 \iff a = 0 \wedge b = 0$ 
  by (metis local.add-0-right zero-sum-right)

```

end

```

context monoid-add
begin

```

An additive monoid gives rise to natural notions of order, which we here define.

```

definition monoid-le (infix  $\leq_m$  50)
where  $a \leq_m b \iff (\exists c. b = a + c)$ 

```

We can also define a subtraction operator that remove a prefix from a monoid, if possible.

```

definition monoid-subtract (infixl  $-_m$  65)
where  $a -_m b = (\text{if } (b \leq_m a) \text{ then } \text{THE } c. a = b + c \text{ else } 0)$ 

```

We derive some basic properties of the preorder

```

lemma monoid-le-least-zero:  $0 \leq_m a$ 
  by (simp add: monoid-le-def)

lemma monoid-le-add:  $a \leq_m a + b$ 
  by (auto simp add: monoid-le-def)

lemma monoid-le-refl:  $a \leq_m a$ 
  by (simp add: monoid-le-def, metis add.right-neutral)

lemma monoid-le-trans:  $\llbracket a \leq_m b; b \leq_m c \rrbracket \implies a \leq_m c$ 
  by (metis add.assoc monoid-le-def)

lemma monoid-le-add-left-mono:  $a \leq_m b \implies c + a \leq_m c + b$ 
  using add-assoc by (auto simp add: monoid-le-def)

```

end

```

class ordered-monoid-pos = monoid-pos + ord +
  assumes le-is-monoid-le:  $a \leq b \longleftrightarrow (a \leq_m b)$ 
  and less-iff:  $a < b \longleftrightarrow a \leq b \wedge \neg (b \leq a)$ 
begin

  subclass preorder
  proof
    fix x y z :: 'a
    show  $(x < y) = (x \leq y \wedge \neg y \leq x)$ 
      by (simp add: local.less-iff)
    show  $x \leq x$ 
      by (simp add: local.le-is-monoid-le local.monoid-le-reft)
    show  $x \leq y \implies y \leq z \implies x \leq z$ 
      using local.le-is-monoid-le local.monoid-le-trans by blast
  qed
end

```

end

1.3 Trace Algebras

A pre-trace algebra is based on a left-cancellative monoid with the additional property that plus has no additive inverse. The latter is required to ensure that there are no “negative traces”. A pre-trace algebra has all the trace algebra axioms, but does not export the definitions of (\leq) and $(-)$.

```

class pre-trace = left-cancel-monoid + monoid-pos
begin

```

From our axiom set, we can derive a variety of properties of the monoid order

```

lemma monoid-le-antisym:
  assumes  $a \leq_m b$   $b \leq_m a$ 
  shows  $a = b$ 
proof -
  obtain a' where  $a': b = a + a'$ 
    using assms(1) monoid-le-def by auto

  obtain b' where  $b': a = b + b'$ 
    using assms(2) monoid-le-def by auto

  have  $b' = (b' + a' + b')$ 
    by (metis a' add-assoc b' local.add-left-imp-eq)

  hence  $a' + b' = 0$ 
    by (metis add-assoc local.add-0-right local.add-left-imp-eq)

  hence  $a' = 0$   $b' = 0$ 
    by (simp add: zero-sum)+

  with a' b' show ?thesis
    by simp
qed

```

The monoid minus operator is also the inverse of plus in this context, as expected.

```

lemma add-monoid-diff-cancel-left [simp]:  $(a + b) -_m a = b$ 
  apply (simp add: monoid-subtract-def monoid-le-add)
  apply (rule the-equality)
  apply (simp)
  using local.add-left-imp-eq apply blast
done

```

Iterating a trace

```

fun tr-iter :: nat  $\Rightarrow$  'a  $\Rightarrow$  'a where
  tr-iter-0: tr-iter 0 t = 0 |
  tr-iter-Suc: tr-iter (Suc n) t = tr-iter n t + t

```

```

lemma tr-iter-empty [simp]: tr-iter m 0 = 0
  by (induct m, simp-all)

```

end

We now construct the trace algebra by also exporting the order and minus operators.

```

class trace = pre-trace + ord + minus +
  assumes le-is-monoid-le:  $a \leq b \longleftrightarrow (a \leq_m b)$ 
  and less-iff:  $a < b \longleftrightarrow a \leq b \wedge \neg (b \leq a)$ 
  and minus-def:  $a - b = a -_m b$ 
begin

```

Next we prove all the trace algebra lemmas.

```

lemma le-iff-add:  $a \leq b \longleftrightarrow (\exists c. b = a + c)$ 
  by (simp add: local.le-is-monoid-le local.monoid-le-def)

```

```

lemma least-zero [simp]:  $0 \leq a$ 
  by (simp add: local.le-is-monoid-le local.monoid-le-least-zero)

```

```

2 Reactive Processes Core Definitions

theory *utp-rea-core*

imports

Trace-Algebra

UTP.utp-concurrency

UTP-Designs.utp-designs

begin recall-syntax

2.1 Alphabet and Signature

The alphabet of reactive processes contains a boolean variable *wait*, which denotes whether a process is exhibiting an intermediate observation. It also has the variable *tr* which denotes

the trace history of a process. The type parameter $'t$ represents the trace model being used, which must form a trace algebra [4], and thus provides the theory of “generalised reactive processes” [4]. The reactive process alphabet also extends the design alphabet, and thus includes the ok variable. For more information on these, see the UTP book [5], or the associated tutorial [2].

alphabet $'t::trace$ $rp\text{-}vars = des\text{-}vars +$
 $wait :: bool$
 $tr :: 't$

type-synonym $('t, ' \alpha) rp = ('t, ' \alpha) rp\text{-}vars\text{-}scheme$

type-synonym $('t, ' \alpha, ' \beta) rel\text{-}rp = (('t, ' \alpha) rp, ('t, ' \beta) rp) urel$

type-synonym $('t, ' \alpha) hrel\text{-}rp = ('t, ' \alpha) rp hrel$

translations

$(type) ('t, ' \alpha) rp \leq (type) ('t, ' \alpha) rp\text{-}vars\text{-}scheme$
 $(type) ('t, ' \alpha) rp \leq (type) ('t, ' \alpha) rp\text{-}vars\text{-}ext$
 $(type) ('t, ' \alpha, ' \beta) rel\text{-}rp \leq (type) (('t, ' \alpha) rp, (' \gamma, ' \beta) rp) urel$
 $(type) ('t, ' \alpha) hrel\text{-}rp \leq (type) ('t, ' \alpha) rp hrel$

As for designs, we set up various types to represent reactive processes. The main types to be used are $('t, ' \alpha, ' \beta) rel\text{-}rp$ and $('t, ' \alpha) hrel\text{-}rp$, which correspond to heterogeneous/homogeneous reactive processes whose trace model is $'t$ and alphabet types are $' \alpha$ and $' \beta$. We also set up some useful syntax translations for these.

notation $rp\text{-}vars.more_L (\Sigma_R)$

syntax

$-svid\text{-}rea\text{-}\alpha :: svid (\Sigma_R)$

translations

3 Events for Reactive Processes

theory *utp-rea-event*
imports *UTP.utp*
begin

3.1 Events

Events of some type ' ϑ ' are just the elements of that type.

type-synonym $'\vartheta \text{ event} = '\vartheta$

3.2 Channels

Typed channels are modelled as functions. Below, $'a$ determines the channel type and $'\vartheta$ the underlying event type. As with values, it is difficult to introduce channels as monomorphic types due to the fact that they can have arbitrary parametrisations in term of $'a$. Applying a channel to an element of its type yields an event, as we may expect. Though this is not formalised here, we may also sensibly assume that all channel- representing functions are injective. Note: is there benefit in formalising this here?

type-synonym $('a, '\vartheta) \text{ chan} = 'a \Rightarrow '\vartheta \text{ event}$

A downside of the approach is that the event type $'\vartheta$ must be able to encode *all* events of a process model, and hence cannot be fixed upfront for a single channel or channel set. To do so, we actually require a notion of ‘extensible’ datatypes, in analogy to extensible record types. Another solution is to encode a notion of channel scoping that namely uses *sum* types to lift channel types into extensible ones, that is using channel-set specific scoping operators. This is a current work in progress.

3.2.1 Operators

The Z type of a channel corresponds to the entire carrier of the underlying HOL type of that channel.

definition $\text{chan-type} :: ('a, '\vartheta) \text{ chan} \Rightarrow 'a \text{ set } (\delta_u)$ **where**
 $[\text{upred-defs}]: \delta_u \ c = \text{UNIV}$

The next lifted function creates an expression that yields a channel event, from an expression on the channel type $'a$.

definition $\text{chan-apply} ::$
 $('a, '\vartheta) \text{ chan} \Rightarrow ('a, '\alpha) \text{ uexpr} \Rightarrow (' \vartheta \text{ event}, '\alpha) \text{ uexpr } ((' \cdot / -)_u)$ **where**

4.2 R2: No dependence upon trace history

There are various ways of expressing *R2*, which are enumerated below.

definition *R2a* :: $(t::trace, '\alpha, '\beta) \text{ rel-rp} \Rightarrow (t, '\alpha, '\beta) \text{ rel-rp}$ **where**
[*upred-defs*]: $R2a(P) = (\bigcap s \cdot P\llbracket \langle\langle s \rangle\rangle, (\langle\langle s \rangle\rangle + (\$tr' - \$tr)) / \$tr, \$tr' \rrbracket)$

definition *R2a'* :: $(t::trace, '\alpha, '\beta) \text{ rel-rp} \Rightarrow (t, '\alpha, '\beta) \text{ rel-rp}$ **where**
[*upred-defs*]: $R2a' P = (R2a(P) \triangleleft R1(true) \triangleright P)$

definition *R2s* :: $(t::trace, '\alpha, '\beta) \text{ rel-rp} \Rightarrow (t, '\alpha, '\beta) \text{ rel-rp}$ **where**
[*upred-defs*]: $R2s(P) = (P\llbracket 0/\$tr \rrbracket\llbracket (\$tr' - \$tr) / \$tr' \rrbracket)$

definition *R2* :: $(t::trace, '\alpha, '\beta) \text{ rel-rp} \Rightarrow (t, '\alpha, '\beta) \text{ rel-rp}$ **where**
[*upred-defs*]: $R2(P) = R1(R2s(P))$

definition *R2c* :: $(t::trace, '\alpha, '\beta) \text{ rel-rp} \Rightarrow (t, '\alpha, '\beta) \text{ rel-rp}$ **where**
[*upred-defs*]: $R2c(P) = (R2s(P) \triangleleft R1(true) \triangleright P)$

R2a and *R2s* are the standard definitions from the UTP book [5]. An issue with these forms is that their definition depends upon *R1* also being satisfied [4], since otherwise the trace minus operator is not well defined. We overcome this with our own version, *R2c*, which applies *R2s* if *R1* holds, and otherwise has no effect. This latter healthiness condition can therefore be reasoned about independently of *R1*, which is useful in some circumstances.

5 Reactive Parallel-by-Merge

```

theory utp-rea-parallel
  imports utp-rea-healths
begin

```

We show closure of parallel by merge under the reactive healthiness conditions by means of suitable restrictions on the merge predicate [4]. We first define healthiness conditions for $R1$ and $R2$ merge predicates.

definition $R1m :: ('t :: trace, 'α) \text{rp merge} \Rightarrow ('t, 'α) \text{rp merge}$
where $[upred-defs]: R1m(M) = (M \wedge \$tr_{<} \leq_u \$tr')$

definition $R1m' :: ('t :: trace, 'α) \text{rp merge} \Rightarrow ('t, 'α) \text{rp merge}$
where $[upred-defs]: R1m'(M) = (M \wedge \$tr_{<} \leq_u \$tr' \wedge \$tr_{<} \leq_u \$0-tr \wedge \$tr_{<} \leq_u \$1-tr)$

A merge predicate can access the history through tr , as usual, but also through $0.tr$ and $1.tr$. Thus we have to remove the latter two histories as well to satisfy $R2$ for the overall construction.

6 Reactive Relations

theory *utp-rea-rel*

imports

utp-rea-healths

UTP-KAT.utp-kleene

begin

This theory defines a reactive relational calculus for $R1$ - $R2$ predicates as an extension of the standard alphabetised predicate calculus. This enables us to formally characterise relational programs that refer to both state variables and a trace history. For more details on reactive relations, please see the associated journal paper [3].

8 Reactive Programs

theory *utp-rea-prog*
imports *utp-rea-cond*
begin

8.1 Stateful reactive alphabet

R3 as presented in the UTP book and related publications is not sensitive to state, although reactive programs often need this property. Thus it is necessary to use a modification of *R3* from Butterfield et al. [1] that explicitly states that intermediate waiting states do not propagate final state variables. In order to do this we need an additional observational variable that captures the program state that we call *st*. Upon this foundation, we can define operators for reactive programs [3].

by (*rel-auto*)

8.3.5 State Abstraction

We introduce state abstraction by creating some lens functors that allow us to lift a lens on the state-space to one on the whole stateful reactive alphabet.

definition *lmap_R* :: $('a \Rightarrow 'b) \Rightarrow ('t::\text{trace}, 'a) \text{ rp} \Rightarrow ('t, 'b) \text{ rp}$ **where**
[lens-defs]: *lmap_R* = *lmap*[*rp-vars*]

This construction lens is useful for conversion between a record and its product representation; it would be helpful if this could be automatically generated.

definition *rsp-make-lens* :: $('s, 't::\text{trace}, 'a) \text{ rsp} \Rightarrow \text{bool} \times \text{bool} \times 't \times 's \times 'a$ **where**
[lens-defs]: *rsp-make-lens* = $(\lambda \text{ lens-get} = \lambda (ok, wait, tr, st, more). (\lambda ok_v = ok, wait_v = wait, tr_v = tr, st_v = st, \dots = more) \lambda \text{ lens-put} = (\lambda s v. (ok_v v, wait_v v, tr_v v, st_v v, more v)))$

lemma *rsp-make-lens-alt*: *rsp-make-lens* = *inv_L* (*ok* +_L *wait* +_L *tr* +_L *st* +_L *rsp-vars.more_L*)

by (auto simp add: lens-defs)

lemma make-lens-bij [simp]: bij-lens rsp-make-lens

by (unfold-locales, simp-all add: lens-defs prod.case-eq-if)

The following is an intuitive definition of the st functorial lens, which frames all the state space excluding st , to which another lens l is applied. We do this by splitting the state space into a product, including the application of l to st , and then invert the product creation lens to reconstruct the reactive state space.

definition map-st-lens ::

$(\sigma \Rightarrow \psi) \Rightarrow$
 $((\sigma, \tau::trace, \alpha) \text{ rsp} \Rightarrow (\psi, \tau::trace, \alpha) \text{ rsp}) \text{ (map'-st}_L\text{) where}$
 $\text{map-st-lens } l = \text{inv}_L (ok +_L \text{wait} +_L \text{tr} +_L \text{st} +_L \text{rsp-vars.more}_L) ;_L$
 $(ok +_L \text{wait} +_L \text{tr} +_L (l ;_L \text{st}) +_L \text{rsp-vars.more}_L)$

The above definition is intuitive, but helpful in proof automaton. Consequently, we the following optimised definition below.

lemma map-st-lens-alt-def [lens-defs]:

$\text{map-st-lens } l = \langle \text{lens-get} = \lambda s. \langle ok_v = ok_v s, \text{wait}_v = \text{wait}_v s, \text{tr}_v = \text{tr}_v s, \text{st}_v = \text{get}_l(\text{st}_v s), \dots$
 $= \text{more } s \rangle$
 $, \text{lens-put} = \lambda s v. \langle ok_v = ok_v v, \text{wait}_v = \text{wait}_v v, \text{tr}_v = \text{tr}_v v, \text{st}_v = \text{put}_l(\text{st}_v s)(\text{st}_v$
 $v), \dots = \text{more } v \rangle \rangle$
 by (auto simp add: map-st-lens-def lens-defs fun-eq-iff)
