Isabelle/UTP: Mechanised Theory Engineering for Unifying Theories of Programming

Simon Foster, Frank Zeyda, Yakoub Nemouchi, Pedro Ribeiro, and Burkhart Wolff
November 6, 2019

Abstract

Isabelle/UTP is a mechanised theory engineering toolkit based on Hoare and He's Unifying Theories of Programming (UTP). UTP enables the creation of denotational, algebraic, and operational semantics for different programming languages using an alphabetised relational calculus. We provide a semantic embedding of the alphabetised relational calculus in Isabelle/HOL, including new type definitions, relational constructors, automated proof tactics, and accompanying algebraic laws. Isabelle/UTP can be used to both capture laws of programming for different languages, and put these fundamental theorems to work in the creation of associated verification tools, using calculi like Hoare logics. This document describes the relational core of the UTP in Isabelle/HOL.

1 Introduction

This document contains the description of our mechanisation of Hoare and He's Unifying Theories of Programming [22, 7] (UTP) in Isabelle/HOL. UTP uses the "programs-as-predicates" approach, pioneered by Hehner [20, 18, 19], to encode denotational semantics and facilitate reasoning about programs. It uses the alphabetised relational calculus, which combines predicate calculus and relation algebra, to denote programs as relations between initial variables (x) and their subsequent values (x'). Isabelle/UTP¹ [16, 28, 15] semantically embeds this relational calculus into Isabelle/HOL, which enables application of the latter's proof facilities to program verification. For an introduction to UTP, we recommend two tutorials [6, 7], and also the UTP book [22].

The Isabelle/UTP core mechanises most of definitions and theorems from chapters 1, 2, 4, and 7 of [22], and some material contained in chapters 5 and 10. This essentially amounts to alphabetised predicate calculus, its core laws, the UTP theory infrastructure, and also parallel-by-merge [22, chapter 5], which adds concurrency primitives. The Isabelle/UTP core does not contain the theory of designs [6] and CSP [7], which are both represented in their own theory developments.

A large part of the mechanisation, however, is foundations that enable these core UTP theories. In particular, Isabelle/UTP builds on our implementation of lenses [16, 14], which gives a formal semantics to state spaces and variables. This, in turn, builds on a previous version of Isabelle/UTP [9, 10], which provided a shallow embedding of UTP by using Isabelle record types to represent alphabets. We follow this approach and, additionally, use the lens laws [11, 16] to characterise well-behaved variables. We also add meta-logical infrastructure for dealing with free variables and substitution. All this, we believe, adds an additional layer rigour to the UTP. The alphabets-as-types approach does impose a number of theoretical limitations. For example, alphabets can only be extended when an injection into a larger state-space type can be exhibited. It is therefore not possible to arbitrarily augment an alphabet with additional variables, but new types must be created to do this. This is largely because as in previous work [9, 10], we actually encode state spaces rather than alphabets, the latter being implicit. Namely, a relation is typed by the state space type that it manipulates, and the alphabet is represented by collection of lenses into this state space. This aspect of our mechanisation is actually much closer to the relational program model in Back's refinement calculus [3].

The pay-off is that the Isabelle/HOL type checker can be directly applied to relational constructions, which makes proof much more automated and efficient. Moreover, our use of lenses mitigates the limitations by providing meta-logical style operators, such as equality on variables, and alphabet membership [16]. Isabelle/UTP can therefore directly harness proof automation from Isabelle/HOL, which allows its use in building efficient verification tools [13, 12]. For a detailed discussion of semantic embedding approaches, please see [28].

In addition to formalising variables, we also make a number of generalisations to UTP laws. Notably, our lens-based representation of state leads us to adopt Back's approach to both assignment and local variables [3]. Assignment becomes a point-free operator that acts on state-space update functions, which provides a rich set of algebraic theorems. Local variables are represented using stacks, unlike in the UTP book where they utilise alphabet extension.

¹Isabelle/UTP website: https://www.cs.york.ac.uk/circus/isabelle-utp/

We give a summary of the main contributions within the Isabelle/UTP core, which can all be seen in the table of contents.

- 1. Formalisation of variables and state-spaces using lenses [16];
- 2. an expression model, together with lifted operators from HOL;
- 3. the meta-logical operators of unrestriction, used-by, substitution, alphabet extrusion, and alphabet restriction;
- 4. the alphabetised predicate calculus and associated algebraic laws;
- 5. the alphabetised relational calculus and associated algebraic laws;
- 6. proof tactics for the above based on interpretation [23];
- 7. a formalisation of UTP theories using locales [4] and building on HOL-Algebra [5];
- 8. Hoare logic [21] and dynamic logic [17];
- 9. weakest precondition and strongest postcondition calculi [8];
- 10. concurrent programming with parallel-by-merge;
- 11. relational operational semantics.

2 UTP Variables

```
\begin{array}{c} \textbf{theory} \ utp\text{-}var\\ \textbf{imports}\\ UTP-Toolkit.utp\text{-}toolkit\\ utp\text{-}parser\text{-}utils\\ \textbf{begin} \end{array}
```

In this first UTP theory we set up variables, which are are built on lenses [11, 16]. A large part of this theory is setting up the parser for UTP variable syntax.

2.1 Initial syntax setup

We will overload the square order relation with refinement and also the lattice operators so we will turn off these notations.

```
purge-notation
```

```
Order.le (infixl \sqsubseteq1 50) and
Lattice.sup (\bigsqcup1- [90] 90) and
Lattice.inf (\bigcap1- [90] 90) and
Lattice.join (infixl \bigsqcup1 65) and
Lattice.meet (infixl \bigcap1 70) and
Set.member (op:) and
Set.member ((-/:-) [51, 51] 50) and
disj (infixr | 30) and
conj (infixr & 35)

declare fst-vwb-lens [simp]
declare snd-vwb-lens [simp]
declare comp-vwb-lens [simp]
```

```
declare lens-inv-bij [simp]
declare id-bij-lens [simp]
declare lens-indep-left-ext [simp]
declare lens-indep-right-ext [simp]
declare lens-comp-quotient [simp]
declare plus-lens-distr [THEN sym, simp]
declare lens-comp-assoc [simp]
```

2.2 Variable foundations

This theory describes the foundational structure of UTP variables, upon which the rest of our model rests. We start by defining alphabets, which following [9, 10] in this shallow model are simply represented as types ' α , though by convention usually a record type where each field corresponds to a variable. UTP variables in this frame are simply modelled as lenses ' $a \Longrightarrow '\alpha$, where the view type 'a is the variable type, and the source type ' α is the alphabet or state-space type.

We define some lifting functions for variables to create input and output variables. These simply lift the alphabet to a tuple type since relations will ultimately be defined by a tuple alphabet.

```
definition in\text{-}var :: ('a \Longrightarrow '\alpha) \Rightarrow ('a \Longrightarrow '\alpha \times '\beta) where [lens\text{-}defs]: in\text{-}var \ x = x \ ;_L \ fst_L
definition out\text{-}var :: ('a \Longrightarrow '\beta) \Rightarrow ('a \Longrightarrow '\alpha \times '\beta) where [lens\text{-}defs]: out\text{-}var \ x = x \ ;_L \ snd_L
```

Variables can also be used to effectively define sets of variables. Here we define the universal alphabet (Σ) to be the bijective lens \mathcal{I}_L . This characterises the whole of the source type, and thus is effectively the set of all alphabet variables.

```
abbreviation (input) univ-alpha :: ('\alpha \Longrightarrow '\alpha) (\Sigma) where univ-alpha \equiv 1_L
```

The next construct is vacuous and simply exists to help the parser distinguish predicate variables from input and output variables.

```
definition pr\text{-}var :: ('a \Longrightarrow '\beta) \Rightarrow ('a \Longrightarrow '\beta) where [lens\text{-}defs]: pr\text{-}var \ x = x
```

2.3 Variable lens properties

We can now easily show that our UTP variable construction are various classes of well-behaved lens .

```
lemma in-var-weak-lens [simp]:
   weak-lens x \Longrightarrow weak-lens (in-var x)
   by (simp add: comp-weak-lens in-var-def)

lemma in-var-semi-uvar [simp]:
   mwb-lens x \Longrightarrow mwb-lens (in-var x)
   by (simp add: comp-mwb-lens in-var-def)

lemma pr-var-weak-lens [simp]:
   weak-lens x \Longrightarrow weak-lens (pr-var x)
   by (simp add: pr-var-def)

lemma pr-var-mwb-lens [simp]:
```

```
mwb-lens x \Longrightarrow mwb-lens (pr-var x)
 by (simp add: pr-var-def)
lemma pr-var-vwb-lens [simp]:
  vwb-lens x \implies vwb-lens (pr-var x)
 by (simp add: pr-var-def)
lemma in-var-uvar [simp]:
  vwb-lens x \implies vwb-lens (in-var x)
 by (simp add: in-var-def)
lemma out-var-weak-lens [simp]:
  weak-lens x \Longrightarrow weak-lens (out-var x)
 by (simp add: comp-weak-lens out-var-def)
lemma out-var-semi-uvar [simp]:
 mwb-lens x \Longrightarrow mwb-lens (out-var x)
 by (simp add: comp-mwb-lens out-var-def)
lemma out-var-uvar [simp]:
  vwb-lens x \Longrightarrow vwb-lens (out-var x)
 by (simp add: out-var-def)
Moreover, we can show that input and output variables are independent, since they refer to
different sections of the alphabet.
lemma in-out-indep [simp]:
 in\text{-}var \ x \bowtie out\text{-}var \ y
 by (simp add: lens-indep-def in-var-def out-var-def fst-lens-def snd-lens-def lens-comp-def)
lemma out-in-indep [simp]:

 by (simp add: pr-var-def)
lemma in-var-plus [simp]: in-var (x +_L y) = in\text{-var } x +_L in\text{-var } y
  by (simp add: in-var-def)
lemma out-var-plus [simp]: out-var (x +_L y) = out-var x +_L out-var y
 by (simp add: out-var-def)
Similar properties follow for sublens
lemma in-var-sublens [simp]:
  y \subseteq_L x \Longrightarrow in\text{-}var \ y \subseteq_L in\text{-}var \ x
 by (metis (no-types, hide-lams) in-var-def lens-comp-assoc sublens-def)
lemma out-var-sublens [simp]:
  y \subseteq_L x \Longrightarrow out\text{-}var \ y \subseteq_L out\text{-}var \ x
 by (metis (no-types, hide-lams) out-var-def lens-comp-assoc sublens-def)
lemma pr-var-sublens-l [simp]: a \subseteq_L b \Longrightarrow pr\text{-var}(a) \subseteq_L b
 by (simp add: pr-var-def)
lemma pr-var-sublens-r [simp]: a \subseteq_L b \Longrightarrow a \subseteq_L pr-var (b)
 by (simp add: pr-var-def)
```

2.4 Lens simplifications

We also define some lookup abstraction simplifications.

```
lemma var-lookup-in [simp]: lens-get (in\text{-}var\ x)\ (A,\ A') = lens\text{-}get\ x\ A by (simp\ add:\ in\text{-}var\text{-}def\ fst\text{-}lens\text{-}def\ lens\text{-}comp\text{-}def)

lemma var-lookup-out [simp]: lens-get (out\text{-}var\ x)\ (A,\ A') = lens\text{-}get\ x\ A' by (simp\ add:\ out\text{-}var\text{-}def\ snd\text{-}lens\text{-}def\ lens\text{-}comp\text{-}def)

lemma var-update-in [simp]: lens-put (in\text{-}var\ x)\ (A,\ A')\ v = (lens\text{-}put\ x\ A\ v,\ A') by (simp\ add:\ in\text{-}var\text{-}def\ fst\text{-}lens\text{-}def\ lens\text{-}comp\text{-}def)

lemma var-update-out [simp]: lens-put (out\text{-}var\ x)\ (A,\ A')\ v = (A,\ lens\text{-}put\ x\ A'\ v) by (simp\ add:\ out\text{-}var\text{-}def\ snd\text{-}lens\text{-}def\ lens\text{-}comp\text{-}def)

lemma var-update va
```

2.5 Syntax translations

In order to support nice syntax for variables, we here set up some translations. The first step is to introduce a collection of non-terminals.

nonterminal svid and svids and svar and svars and salpha

These non-terminals correspond to the following syntactic entities. Non-terminal *svid* is an atomic variable identifier, and *svids* is a list of identifier. *svar* is a decorated variable, such as an input or output variable, and *svars* is a list of decorated variables. *salpha* is an alphabet or set of variables. Such sets can be constructed only through lens composition due to typing restrictions. Next we introduce some syntax constructors.

```
syntax — Identifiers
```

```
-svid :: id-position \Rightarrow svid (- [999] 999)

-svlongid :: longid-position \Rightarrow svid (- [999] 999)

-svid-unit :: svid \Rightarrow svids (-)

-svid-list :: svid \Rightarrow svids \Rightarrow svids (-,/ -)

-svid-alpha :: svid \Rightarrow svid \Rightarrow svid (-:- [999,998] 998)

-svid-res :: svid \Rightarrow svid \Rightarrow svid (-|- [999,998] 998)

-mk-svid-list :: svids \Rightarrow logic — Helper function for summing a list of identifiers

-svid-view :: logic \Rightarrow svid (\mathcal{V}[-]) — View of a symmetric lens

-svid-coview :: logic \Rightarrow svid (\mathcal{V}[-]) — Coview of a symmetric lens
```

A variable identifier can either be a HOL identifier, the complete set of variables in the alphabet \mathbf{v} , or a composite identifier separated by colons, which corresponds to a sort of qualification. The final option is effectively a lens composition.

```
\begin{array}{ll} \mathbf{syntax} & - \text{ Decorations} \\ -spvar & :: svid \Rightarrow svar \left(\& - [990] \ 990\right) \end{array}
```

-sinvar :: $svid \Rightarrow svar (\$-[990] 990)$ -soutvar :: $svid \Rightarrow svar (\$-[990] 990)$

A variable can be decorated with an ampersand, to indicate it is a predicate variable, with a dollar to indicate its an unprimed relational variable, or a dollar and "acute" symbol to indicate its a primed relational variable. Isabelle's parser is extensible so additional decorations can be and are added later.

```
syntax — Variable sets

-salphaid :: svid \Rightarrow salpha \ (-[990] \ 990)

-salphavar :: svar \Rightarrow salpha \ (-[990] \ 990)
```

```
-salphaparen :: salpha \Rightarrow salpha ('(-'))

-salphacomp :: salpha \Rightarrow salpha \Rightarrow salpha (infixr; 75)

-salphaprod :: salpha \Rightarrow salpha (infixr \times 85)

-salpha-all :: salpha (\Sigma)

-salpha-none :: salpha (\emptyset)

-svar-nil :: svar \Rightarrow svars (-)

-svar-cons :: svar \Rightarrow svars \Rightarrow svars (-,/ -)

-salphaset :: svars \Rightarrow salpha ({-})

-salphamk :: logic \Rightarrow salpha
```

The terminals of an alphabet are either HOL identifiers or UTP variable identifiers. We support two ways of constructing alphabets; by composition of smaller alphabets using a semi-colon or by a set-style construction $\{a, b, c\}$ with a list of UTP variables.

```
syntax — Quotations

-ualpha-set :: svars \Rightarrow logic (\{-\}_{\alpha})

-svar :: svar \Rightarrow logic ('(-')_v)
```

For various reasons, the syntax constructors above all yield specific grammar categories and will not parser at the HOL top level (basically this is to do with us wanting to reuse the syntax for expressions). As a result we provide some quotation constructors above.

Next we need to construct the syntax translations rules. Finally, we set up the translations rules.

translations

```
    Identifiers

-svid \ x \rightharpoonup x
-svlongid x \rightharpoonup x
-svid-alpha \rightleftharpoons \Sigma

The translation rules mainly convert syntax into lens constructions, using a mixture of lens operators and the bespoke variable definitions. Notably, a colon variable identifier qualification becomes a lens composition, and variable sets are constructed using len sum. The translation rules are carefully crafted to ensure both parsing and pretty printing.

Finally we create the following useful utility translation function that allows us to construct a UTP variable (lens) type given a return and alphabet type.

```
syntax
```

end

```
-uvar-ty :: type \Rightarrow type

parse-translation (
let

fun uvar-ty-tr [ty] = Syntax.const @{type-syntax lens} $ ty $ Syntax.const @{type-syntax dummy} | uvar-ty-tr ts = raise TERM (uvar-ty-tr, ts);

in [(@{syntax-const -uvar-ty}, K uvar-ty-tr)] end
}
```

3 UTP Expressions

```
theory utp-expr
imports
utp-var
begin
```

3.1 Expression type

```
purge-notation BNF-Def.convol (\langle (-,/-) \rangle)
```

Before building the predicate model, we will build a model of expressions that generalise alphabetised predicates. Expressions are represented semantically as mapping from the alphabet ' α to the expression's type 'a. This general model will allow us to unify all constructions under one type. The majority definitions in the file are given using the *lifting* package [23], which allows us to reuse much of the existing library of HOL functions.

```
typedef ('t, '\alpha) uexpr = UNIV :: ('\alpha \Rightarrow 't) set ...
```

setup-lifting type-definition-uexpr

```
notation Rep\text{-}uexpr (\llbracket - \rrbracket_e) notation Abs\text{-}uexpr (mk_e)
```

nonterminal uexp and uexprs

```
lemma uexpr-eq-iff:

e = f \longleftrightarrow (\forall b. [e]_e b = [f]_e b)

using Rep-uexpr-inject[of e f, THEN sym] by (auto)
```

The term $[e]_e$ b effectively refers to the semantic interpretation of the expression under the state-space valuation (or variables binding) b. It can be used, in concert with the lifting package, to interpret UTP constructs to their HOL equivalents. We create some theorem sets to store such transfer theorems.

named-theorems uexpr-defs and ueval and lit-simps and lit-norm

3.2 Core expression constructs

A variable expression corresponds to the lens *get* function associated with a variable. Specifically, given a lens the expression always returns that portion of the state-space referred to by the lens.

```
lift-definition var :: ('t \Longrightarrow '\alpha) \Rightarrow ('t, '\alpha) \ uexpr \ \textbf{is} \ lens-get \ \textbf{.}
```

A literal is simply a constant function expression, always returning the same value for any binding.

```
lift-definition lit :: t \Rightarrow (t, \alpha) \ uexpr (\ll-\gg) is \lambda \ v \ b. \ v.
```

The following operator is the general function application for expressions.

```
lift-definition uexpr-appl :: ('a \Rightarrow 'b, 's) \ uexpr \Rightarrow ('a, 's) \ uexpr \Rightarrow ('b, 's) \ uexpr \ (infixl |> 85) is \lambda f x s. f s \ (x s).
```

We define lifting for unary, binary, ternary, and quaternary expression constructs, that simply take a HOL function with correct number of arguments and apply it function to all possible results of the expressions.

```
abbreviation uop :: ('a \Rightarrow 'b) \Rightarrow ('a, '\alpha) \ uexpr \Rightarrow ('b, '\alpha) \ uexpr where uop \ f \ e \equiv \langle f \rangle \ | > \ e
```

 $declare [[coercion-map \ uop]] - uop$ is useful as a coercion map

```
abbreviation bop ::
```

```
('a \Rightarrow 'b \Rightarrow 'c) \Rightarrow ('a, '\alpha) \ uexpr \Rightarrow ('b, '\alpha) \ uexpr \Rightarrow ('c, '\alpha) \ uexpr
where bop \ f \ u \ v \equiv \langle f \rangle \ |> \ u \ |> \ v
```

 ${f abbreviation}\ trop::$

```
('a \Rightarrow 'b \Rightarrow 'c \Rightarrow 'd) \Rightarrow ('a, '\alpha) \ uexpr \Rightarrow ('b, '\alpha) \ uexpr \Rightarrow ('c, '\alpha) \ uexpr \Rightarrow ('d, '\alpha) \ uexpr \Rightarrow ('d, '\alpha) \ uexpr \Rightarrow ('d, 'a) \ uexpr \Rightarrow ('d, 'a)
```

abbreviation qtop ::

```
('a \Rightarrow 'b \Rightarrow 'c \Rightarrow 'd \Rightarrow 'e) \Rightarrow

('a, '\alpha) \ uexpr \Rightarrow ('b, '\alpha) \ uexpr \Rightarrow ('c, '\alpha) \ uexpr \Rightarrow ('d, '\alpha) \ uexpr \Rightarrow

('e, '\alpha) \ uexpr

where qtop \ fu \ v \ w \ x \equiv \langle f \rangle \ |> u \ |> v \ |> w \ |> x
```

We also define a UTP expression version of function (λ) abstraction, that takes a function producing an expression and produces an expression producing a function.

```
lift-definition uabs :: ('a \Rightarrow ('b, '\alpha) \ uexpr) \Rightarrow ('a \Rightarrow 'b, '\alpha) \ uexpr is \lambda \ f \ A \ x. \ f \ x \ A.
```

We set up syntax for the conditional. This is effectively an infix version of if-then-else where the condition is in the middle.

```
definition uIf :: bool \Rightarrow 'a \Rightarrow 'a \Rightarrow 'a \text{ where} [uexpr-defs]: uIf = If

abbreviation cond ::
('a,'\alpha) \ uexpr \Rightarrow (bool, '\alpha) \ uexpr \Rightarrow ('a,'\alpha) \
```

UTP expression is equality is simply HOL equality lifted using the *bop* binary expression constructor.

```
abbreviation (input) eq-upred :: ('a, '\alpha) uexpr \Rightarrow ('a, '\alpha) uexpr \Rightarrow (bool, '\alpha) uexpr (infixl =u 50) where eq-upred x \ y \equiv bop \ HOL.eq \ x \ y
```

A literal is the expression $\ll v \gg$, where v is any HOL term. Actually, the literal construct is very versatile and also allows us to refer to HOL variables within UTP expressions, and has a variety of other uses. It can therefore also be considered as a kind of quotation mechanism. We also set up syntax for UTP variable expressions.

```
syntax
```

```
-uuvar :: svar \Rightarrow logic (-)

translations
-uuvar x == CONST var x
```

Since we already have a parser for variables, we can directly reuse it and simply apply the *var* expression construct to lift the resulting variable to an expression.

3.3 Type class instantiations

Isabelle/HOL of course provides a large hierarchy of type classes that provide constructs such as numerals and the arithmetic operators. Fortunately we can directly make use of these for UTP expressions, and thus we now perform a long list of appropriate instantiations. We first lift the core arithmetic constants and operators using a mixture of literals, unary, and binary expression constructors.

```
instantiation uexpr :: (zero, type) zero
begin
  definition zero-uexpr-def [uexpr-defs]: 0 = lit 0
instance ..
end

instantiation uexpr :: (one, type) one
begin
  definition one-uexpr-def [uexpr-defs]: 1 = lit 1
instance ..
end
instantiation uexpr :: (plus, type) plus
```

```
begin definition plus-uexpr-def [uexpr-defs]: u + v = bop \ (+) \ u \ v instance .. end instance uexpr :: (semigroup-add, type) semigroup-add by (intro-classes) (simp add: plus-uexpr-def zero-uexpr-def, transfer, simp add: add.assoc)+
```

The following instantiation sets up numerals. This will allow us to have Isabelle number representations (i.e. 3,7,42,198 etc.) to UTP expressions directly.

```
instance uexpr :: (numeral, type) numeral
by (intro-classes, simp add: plus-uexpr-def, transfer, simp add: add.assoc)
```

We can also define the order relation on expressions. Now, unlike the previous group and ring constructs, the order relations (\leq) and (\leq) return a *bool* type. This order is not therefore the lifted order which allows us to compare the valuation of two expressions, but rather the order on expressions themselves. Notably, this instantiation will later allow us to talk about predicate refinements and complete lattices.

```
instantiation uexpr :: (ord, type) \ ord begin lift-definition less-eq\text{-}uexpr :: ('a, 'b) \ uexpr \Rightarrow ('a, 'b) \ uexpr \Rightarrow bool is \lambda \ P \ Q. \ (\forall \ A. \ P \ A \leq Q \ A). definition less\text{-}uexpr :: ('a, 'b) \ uexpr \Rightarrow ('a, 'b) \ uexpr \Rightarrow bool where [uexpr\text{-}defs]: less\text{-}uexpr \ P \ Q = (P \leq Q \land \neg \ Q \leq P) instance .. end
```

UTP expressions whose return type is a partial ordered type, are also partially ordered as the following instantiation demonstrates.

```
instance uexpr :: (order, type) order proof

fix x \ y \ z :: ('a, 'b) uexpr

show (x < y) = (x \le y \land \neg y \le x) by (simp add: less-uexpr-def)

show x \le x by (transfer, auto)

show x \le y \Longrightarrow y \le z \Longrightarrow x \le z

by (transfer, blast intro:order.trans)

show x \le y \Longrightarrow y \le x \Longrightarrow x = y

by (transfer, rule ext, simp add: eq-iff)

qed
```

3.4 Syntax translations

The follows a large number of translations that lift HOL functions to UTP expressions using the various expression constructors defined above. Much of the time we try to keep the HOL syntax but add a "u" subscript.

```
abbreviation (input) ulens-override x f g \equiv lens-override f g x
```

This operator allows us to get the characteristic set of a type. Essentially this is *UNIV*, but it retains the type syntactically for pretty printing.

```
definition set-of :: 'a itself \Rightarrow 'a set where [uexpr-defs]: set-of t = UNIV
```

We add new non-terminals for UTP tuples and maplets.

nonterminal utuple-args and umaplet and umaplets

```
syntax — Core expression constructs

abbreviation (input) ugeq (infix \geq_u 50) where x \geq_u y \equiv y \leq_u x
```

3.5 Evaluation laws for expressions

The following laws show how to evaluate the core expressions constructs in terms of which the above definitions are defined. Thus, using these theorems together, we can convert any UTP expression into a pure HOL expression. All these theorems are marked as *ueval* theorems which can be used for evaluation.

```
lemma lit-ueval [ueval]: [\![ \langle x \rangle ]\!]_e b = x
by (transfer, simp)
lemma var-ueval [ueval]: [\![ var \ x ]\!]_e b = get_x b
by (transfer, simp)
lemma appl-ueval [ueval]: [\![ f \ | > x ]\!]_e b = [\![ f ]\!]_e b ([\![ x ]\!]_e b)
by (transfer, simp)
```

3.6 Misc laws

We also prove a few useful algebraic and expansion laws for expressions.

```
lemma uop-const [simp]: uop id u = u
by (transfer, simp)
lemma bop-const-1 [simp]: bop (\lambda x \ y. \ y) u \ v = v
by (transfer, simp)
lemma bop-const-2 [simp]: bop (\lambda x \ y. \ x) u \ v = u
by (transfer, simp)
lemma uexpr-fst [simp]: \pi_1((e, f)_u) = e
by (transfer, simp)
lemma uexpr-snd [simp]: \pi_2((e, f)_u) = f
by (transfer, simp)
```

3.7 Literalise tactics

The following tactic converts literal HOL expressions to UTP expressions and vice-versa via a collection of simplification rules. The two tactics are called "literalise", which converts UTP to expressions to HOL expressions – i.e. it pushes them into literals – and unliteralise that reverses this. We collect the equations in a theorem attribute called "lit_simps".

```
lemma lit-fun-simps [lit-simps]:

«i \ x \ y \ z \ u \gg = qtop \ i \ «x \gg «y \gg «z \gg «u \gg h \ x \ y \ z \gg = trop \ h \ «x \gg «y \gg «z \gg uop \ g \ «x \gg «y \gg uop \ f \ x \gg = uop \ f \ «x \gg uop \ f \ x \gg uop \ u
```

The following two theorems also set up interpretation of numerals, meaning a UTP numeral can always be converted to a HOL numeral.

```
lemma numeral-uexpr-rep-eq [ueval]: [[numeral x]]_e b = numeral x apply (induct x) apply (simp add: lit.rep-eq one-uexpr-def) apply (simp add: ueval numeral-Bit0 plus-uexpr-def) apply (simp add: ueval numeral-Bit1 plus-uexpr-def one-uexpr-def) done lemma numeral-uexpr-simp: numeral x = «numeral x > by (simp add: uexpr-eq-iff numeral-uexpr-rep-eq lit.rep-eq) lemma lit-zero [lit-simps]: «0» = 0 by (simp add:uexpr-defs) lemma lit-one [lit-simps]: «1» = 1 by (simp add: uexpr-defs) lemma lit-plus [lit-simps]: «x + y > = «x > + «y > by (simp add: uexpr-defs, transfer, simp) lemma lit-numeral [lit-simps]: «numeral n >  = numeral n > by (simp add: numeral-uexpr-simp)
```

In general unliteralising converts function applications to corresponding expression liftings. Since some operators, like + and *, have specific operators we also have to use uIf = If

```
0 = \langle 0 :: ?'a \rangle
1 = \langle 1 :: ?'a \rangle
?u + ?v = bop (+) ?u ?v
```

```
(?P < ?Q) = (?P \le ?Q \land \neg ?Q \le ?P)
```

set-of ?t = UNIV in reverse to correctly interpret these. Moreover, numerals must be handled separately by first simplifying them and then converting them into UTP expression numerals; hence the following two simplification rules.

```
lemma lit-numeral-1: uop numeral x = Abs-uexpr (\lambda b. \ numeral \ (\llbracket x \rrbracket_e \ b))
by (simp \ add: \ uexpr-appl-def \ lit.rep-eq)

lemma lit-numeral-2: Abs-uexpr (\lambda \ b. \ numeral \ v) = numeral \ v
by (metis \ lit.abs-eq lit-numeral)

method literalise = (unfold \ lit-simps [THEN \ sym])
method unliteralise = (unfold \ lit-simps uexpr-defs [THEN \ sym];
(unfold \ lit-numeral-1; (unfold \ uexpr-defs ueval); (unfold \ lit-numeral-2))?)+
```

The following tactic can be used to evaluate literal expressions. It first literalises UTP expressions, that is pushes as many operators into literals as possible. Then it tries to simplify, and final unliteralises at the end.

method uexpr-simp uses simps = ((literalise)?, simp add: lit-norm simps, (unliteralise)?)

```
lemma (1::(int, '\alpha) uexpr) + \ll2> = 4 \longleftrightarrow \ll3> = 4 apply (literalise) apply (uexpr-simp) oops
```

end

4 Expression Type Class Instantiations

```
theory utp-expr-insts
imports utp-expr
begin
```

It should be noted that instantiating the unary minus class, *uminus*, will also provide negation UTP predicates later.

```
instantiation uexpr :: (uminus, type) \ uminus
begin
   definition uminus - uexpr - def \ [uexpr - defs] : - u = uop \ uminus \ u
instance ..
end

instantiation uexpr :: (minus, type) \ minus
begin
   definition minus - uexpr - def \ [uexpr - defs] : u - v = bop \ (-) \ u \ v
instance ..
end

instantiation uexpr :: (times, type) \ times
begin
   definition times - uexpr - def \ [uexpr - defs] : u * v = bop \ times \ u \ v
instance ..
end
```

```
instance uexpr :: (Rings.dvd, type) Rings.dvd..
instantiation uexpr :: (divide, type) divide
begin
 definition divide-uexpr :: ('a, 'b) uexpr \Rightarrow ('a, 'b) uexpr \Rightarrow ('a, 'b) uexpr where
 [uexpr-defs]: divide-uexpr\ u\ v=bop\ divide\ u\ v
end
instantiation uexpr :: (inverse, type) inverse
 definition inverse-uexpr :: ('a, 'b) uexpr \Rightarrow ('a, 'b) uexpr
 where [uexpr-defs]: inverse-uexpr\ u = uop\ inverse\ u
instance ..
end
instantiation uexpr :: (modulo, type) modulo
 definition mod\text{-}uexpr\text{-}def [uexpr\text{-}defs]: u mod v = bop (mod) u v
instance ...
end
instantiation uexpr :: (sgn, type) \ sgn
 definition sgn\text{-}uexpr\text{-}def [uexpr\text{-}defs]: sgn\ u = uop\ sgn\ u
instance ..
end
instantiation uexpr :: (abs, type) abs
 definition abs-uexpr-def [uexpr-defs]: abs u = uop abs u
instance ..
end
Once we've set up all the core constructs for arithmetic, we can also instantiate the type classes
for various algebras, including groups and rings. The proofs are done by definitional expansion,
the transfer tactic, and then finally the theorems of the underlying HOL operators. This is
mainly routine, so we don't comment further.

5 Unrestriction

theory utp-unrest imports utp-expr-insts begin

5.1 Definitions and Core Syntax

Unrestriction is an encoding of semantic freshness that allows us to reason about the presence of variables in predicates without being concerned with abstract syntax trees. An expression p is unrestricted by lens x, written $x \not\equiv p$, if altering the value of x has no effect on the valuation of p. This is a sufficient notion to prove many laws that would ordinarily rely on an fv function.

Unrestriction was first defined in the work of Marcel Oliveira [27, 26] in his UTP mechanisation in *ProofPowerZ*. Our definition modifies his in that our variables are semantically characterised as lenses, and supported by the lens laws, rather than named syntactic entities. We effectively fuse the ideas from both Feliachi [9] and Oliveira's [26] mechanisations of the UTP, the former being also purely semantic in nature.

We first set up overloaded syntax for unrestriction, as several concepts will have this defined.

```
consts
```

```
unrest :: 'a \Rightarrow 'b \Rightarrow bool

syntax
-unrest :: salpha \Rightarrow logic \Rightarrow logic \Rightarrow logic (infix $\sharp$ 20)

translations
-unrest \ x \ p == CONST \ unrest \ x \ p
-unrest \ (-salphaset \ (-salphamk \ (x +_L \ y))) \ P <= -unrest \ (x +_L \ y) \ P
```

Our syntax translations support both variables and variable sets such that we can write down predicates like &x \sharp P and also {&x, &y, &z} \sharp P.

We set up a simple tactic for discharging unrestriction conjectures using a simplification set.

```
named-theorems unrest
method unrest-tac = (simp add: unrest)?
```

Unrestriction for expressions is defined as a lifted construct using the underlying lens operations. It states that lens x is unrestricted by expression e provided that, for any state-space binding e and variable valuation e, the value which the expression evaluates to is unaltered if we set e to e in e. In other words, we cannot effect the behaviour of e by changing e. Thus e does not

observe the portion of state-space characterised by x. We add this definition to our overloaded constant.

```
lift-definition unrest-uexpr :: ('a \Longrightarrow '\alpha) \Rightarrow ('b, '\alpha) \ uexpr \Rightarrow bool is \lambda \ x \ e. \ \forall \ b \ v. \ e \ (put_x \ b \ v) = e \ b.

adhoc-overloading unrest unrest-uexpr

lemma unrest-expr-alt-def: weak-lens x \Longrightarrow (x \ \sharp \ P) = (\forall \ b \ b'. \ \llbracket P \rrbracket_e \ (b \oplus_L \ b' \ on \ x) = \llbracket P \rrbracket_e \ b) by (transfer, metis lens-override-def weak-lens.put-get)
```

5.2 Unrestriction laws

We now prove unrestriction laws for the key constructs of our expression model. Many of these depend on lens properties and so variously employ the assumptions mwb-lens and vwb-lens, depending on the number of assumptions from the lenses theory is required.

Firstly, we prove a general property – if x and y are both unrestricted in P, then their composition is also unrestricted in P. One can interpret the composition here as a union – if the two sets of variables x and y are unrestricted, then so is their union.

```
lemma unrest-var-comp [unrest]:
[\![ x \sharp P; y \sharp P ]\!] \Longrightarrow x;y \sharp P
by (transfer, simp add: lens-defs)

lemma unrest-svar [unrest]: (\&x \sharp P) \longleftrightarrow (x \sharp P)
by (transfer, simp add: lens-defs)

lemma unrest-lens-comp [unrest]: x \sharp e \Longrightarrow x:y \sharp e
by (simp add: lens-comp-def unrest-uexpr.rep-eq)
```

No lens is restricted by a literal, since it returns the same value for any state binding.

```
lemma unrest-lit [unrest]: x \sharp \ll v \gg
by (transfer, simp)
```

If one lens is smaller than another, then any unrestriction on the larger lens implies unrestriction on the smaller.

```
lemma unrest-sublens:

fixes P :: ('a, '\alpha) \ uexpr

assumes x \not\parallel P y \subseteq_L x

shows y \not\parallel P

using assms

by (transfer, metis (no-types, lifting) lens.select-convs(2) lens-comp-def sublens-def)
```

If two lenses are equivalent, and thus they characterise the same state-space regions, then clearly unrestrictions over them are equivalent.

```
lemma unrest-equiv:

fixes P :: ('a, '\alpha) \ uexpr

assumes mwb-lens y \ x \approx_L y \ x \ \sharp \ P

shows y \ \sharp \ P

by (metis assms lens-equiv-def sublens-pres-mwb sublens-put-put unrest-uexpr.rep-eq)
```

If we can show that an expression is unrestricted on a bijective lens, then is unrestricted on the entire state-space.

```
\mathbf{lemma}\ \mathit{bij-lens-unrest-all}\colon
 fixes P :: ('a, '\alpha) \ uexpr
 assumes bij-lens X X \sharp P
 shows \Sigma \sharp P
 using assms bij-lens-equiv-id lens-equiv-def unrest-sublens by blast
lemma bij-lens-unrest-all-eq:
 fixes P :: ('a, '\alpha) \ uexpr
 assumes bij-lens X
 shows (\Sigma \sharp P) \longleftrightarrow (X \sharp P)
 by (meson assms bij-lens-equiv-id lens-equiv-def unrest-sublens)
If an expression is unrestricted by all variables, then it is unrestricted by any variable
{f lemma}\ unrest-all-var:
 fixes e :: ('a, '\alpha) \ uexpr
 assumes \Sigma \sharp e
 shows x \sharp e
 by (metis assms id-lens-def lens.simps(2) unrest-uexpr.rep-eq)
We can split an unrestriction composed by lens plus
{f lemma} unrest	ext{-}plus	ext{-}split:
 fixes P :: ('a, '\alpha) \ uexpr
 assumes x \bowtie y vwb-lens x vwb-lens y
 shows unrest (x +_L y) P \longleftrightarrow (x \sharp P) \land (y \sharp P)
 using assms
 by (meson lens-plus-right-sublens lens-plus-ub sublens-refl unrest-sublens unrest-var-comp vwb-lens-wb)
The following laws demonstrate the primary motivation for lens independence: a variable ex-
pression is unrestricted by another variable only when the two variables are independent. Lens
independence thus effectively allows us to semantically characterise when two variables, or sets
of variables, are different.
lemma unrest-var [unrest]: \llbracket mwb-lens x; x \bowtie y \rrbracket \implies y \sharp var x
 by (transfer, auto)
lemma unrest-iuvar [unrest]: \llbracket mwb-lens x; x \bowtie y \rrbracket \Longrightarrow \$y \sharp \$x
 by (simp add: unrest-var)
lemma unrest-ouvar [unrest]: \llbracket mwb-lens x; x \bowtie y \rrbracket \Longrightarrow \$y' \sharp \$x'
 by (simp add: unrest-var)
The following laws follow automatically from independence of input and output variables.
lemma unrest-iuvar-ouvar [unrest]:
 fixes x :: ('a \Longrightarrow '\alpha)
 assumes mwb-lens y
 shows \$x \sharp \$y
 by (metis prod.collapse unrest-uexpr.rep-eq var.rep-eq var-lookup-out var-update-in)
lemma unrest-ouvar-iuvar [unrest]:
 fixes x :: ('a \Longrightarrow '\alpha)
 assumes mwb-lens y
 shows x' \sharp y
 by (metis prod.collapse unrest-uexpr.rep-eq var.rep-eq var-lookup-in var-update-out)
```

Unrestriction distributes through the various function lifting expression constructs; this allows us to prove unrestrictions for the majority of the expression language.

```
lemma unrest-appl [unrest]: [\![x \sharp f; x \sharp v]\!] \Longrightarrow x \sharp f > v
 by (transfer, simp)
lemma unrest-uop [unrest]: x \sharp e \Longrightarrow x \sharp uop f e
 by (simp add: unrest)
lemma unrest-bop [unrest]: [x \sharp u; x \sharp v] \implies x \sharp bop f u v
 by (simp add: unrest)
lemma unrest-trop [unrest]: [x \sharp u; x \sharp v; x \sharp w] \Longrightarrow x \sharp trop f u v w
 by (simp add: unrest)
\mathbf{lemma} \ unrest\text{-}qtop \ [unrest] \colon \llbracket \ x \ \sharp \ u; \ x \ \sharp \ v; \ x \ \sharp \ w; \ x \ \sharp \ y \ \rrbracket \Longrightarrow x \ \sharp \ qtop \ f \ u \ v \ w \ y
 by (simp add: unrest)
For convenience, we also prove unrestriction rules for the bespoke operators on equality, num-
bers, arithmetic etc.
lemma unrest-zero [unrest]: x \sharp \theta
 by (simp add: unrest-lit zero-uexpr-def)

 by (simp add: divide-uexpr-def unrest)
lemma unrest-case-prod [unrest]: \llbracket \bigwedge i j. x \sharp P i j \rrbracket \implies x \sharp case-prod P v
  by (simp add: prod.split-sel-asm)
For a \lambda-term we need to show that the characteristic function expression does not restrict v for
any input value x.
lemma unrest-ulam [unrest]:
  \llbracket \bigwedge x. \ v \sharp F x \rrbracket \Longrightarrow v \sharp (\lambda \ x \cdot F x)
 by (transfer, simp)
```

6 Used-by

```
theory utp-usedby imports utp-unrest begin
```

The used-by predicate is the dual of unrestriction. It states that the given lens is an upper-bound on the size of state space the given expression depends on. It is similar to stating that the lens is a valid alphabet for the predicate. For convenience, and because the predicate uses a similar form, we will reuse much of unrestriction's infrastructure.

```
consts
 usedBy :: 'a \Rightarrow 'b \Rightarrow bool
syntax
 -usedBy :: salpha \Rightarrow logic \Rightarrow logic \Rightarrow logic  (infix \ 20)
translations

7 UTP Tactics

declare image-comp [simp]

```
theory utp-tactics
imports
utp-expr utp-unrest utp-usedby
keywords update-uexpr-rep-eq-thms :: thy-decl
begin
```

In this theory, we define several automatic proof tactics that use transfer techniques to reinterpret proof goals about UTP predicates and relations in terms of pure HOL conjectures. The fundamental tactics to achieve this are *pred-simp* and *rel-simp*; a more detailed explanation of their behaviour is given below. The tactics can be given optional arguments to fine-tune their behaviour. By default, they use a weaker but faster form of transfer using rewriting; the option *robust*, however, forces them to use the slower but more powerful transfer of Isabelle's lifting package. A second option *no-interp* suppresses the re-interpretation of state spaces in order to

In addition to *pred-simp* and *rel-simp*, we also provide the tactics *pred-auto* and *rel-auto*, as well as *pred-blast* and *rel-blast*; they, in essence, sequence the simplification tactics with the methods *auto* and *blast*, respectively.

7.1 Theorem Attributes

The following named attributes have to be introduced already here since our tactics must be able to see them. Note that we do not want to import the theories *utp-pred* and *utp-rel* here, so that both can potentially already make use of the tactics we define in this theory.

```
named-theorems upred-defs upred definitional theorems named-theorems urel-defs urel definitional theorems
```

eradicate record for tuple types prior to automatic proof.

7.2 Generic Methods

We set up several automatic tactics that recast theorems on UTP predicates into equivalent HOL predicates, eliminating artefacts of the mechanisation as much as this is possible. Our approach is first to unfold all relevant definition of the UTP predicate model, then perform a transfer, and finally simplify by using lens and variable definitions, the split laws of alphabet records, and interpretation laws to convert record-based state spaces into products. The definition of the respective methods is facilitated by the Eisbach tool: we define generic methods that are parametrised by the tactics used for transfer, interpretation and subsequent automatic proof. Note that the tactics only apply to the head goal.

Generic Predicate Tactics

```
method gen-pred-tac methods transfer-tac interp-tac prove-tac = (
    ((unfold upred-defs) [1])?;
    (transfer-tac),
    (simp add: fun-eq-iff
        lens-defs upred-defs alpha-splits Product-Type.split-beta)?,
    (interp-tac)?);
    (prove-tac)
```

Generic Relational Tactics

```
method gen-rel-tac methods transfer-tac interp-tac prove-tac = (
    ((unfold upred-defs urel-defs) [1])?;
    (transfer-tac),
    (simp add: fun-eq-iff relcomp-unfold OO-def
    lens-defs upred-defs alpha-splits Product-Type.split-beta)?,
    (interp-tac)?);
    (prove-tac)
```

7.3 Transfer Tactics

Next, we define the component tactics used for transfer.

7.3.1 Robust Transfer

Robust transfer uses the transfer method of the lifting package.

```
method slow-uexpr-transfer = (transfer)
```

7.3.2 Faster Transfer

Fast transfer side-steps the use of the (transfer) method in favour of plain rewriting with the underlying rep-eq-... laws of lifted definitions. For moderately complex terms, surprisingly, the transfer step turned out to be a bottle-neck in some proofs; we observed that faster transfer resulted in a speed-up of approximately 30% when building the UTP theory heaps. On the downside, tactics using faster transfer do not always work but merely in about 95% of the cases. The approach typically works well when proving predicate equalities and refinements conjectures.

A known limitation is that the faster tactic, unlike lifting transfer, does not turn free variables into meta-quantified ones. This can, in some cases, interfere with the interpretation step and cause subsequent application of automatic proof tactics to fail. A fix is in progress [TODO].

Attribute Setup We first configure a dynamic attribute *uexpr-rep-eq-thms* to automatically collect all *rep-eq-* laws of lifted definitions on the *uexpr* type.

```
ML-file uexpr-rep-eq.ML

setup (
Global-Theory.add-thms-dynamic (@{binding uexpr-rep-eq-thms}),
uexpr-rep-eq.get-uexpr-rep-eq-thms o Context.theory-of)
```

We next configure a command **update-uexpr-rep-eq-thms** in order to update the content of the *uexpr-rep-eq-thms* attribute. Although the relevant theorems are collected automatically, for efficiency reasons, the user has to manually trigger the update process. The command must hence be executed whenever new lifted definitions for type *uexpr* are created. The updating mechanism uses **find-theorems** under the hood.

```
ML (
Outer-Syntax.command @{command-keyword update-uexpr-rep-eq-thms})
reread and update content of the uexpr-rep-eq-thms attribute
(Scan.succeed (Toplevel.theory uexpr-rep-eq.read-uexpr-rep-eq-thms));
)
```

update-uexpr-rep-eq-thms — Read *uexpr-rep-eq-thms* here.

Lastly, we require several named-theorem attributes to record the manual transfer laws and extra simplifications, so that the user can dynamically extend them in child theories.

named-theorems uexpr-transfer-laws uexpr transfer laws

```
declare uexpr-eq-iff [uexpr-transfer-laws]
named-theorems uexpr-transfer-extra extra simplifications for uexpr transfer
declare unrest-uexpr.rep-eq [uexpr-transfer-extra]
```

```
usedBy-uexpr.rep-eq [uexpr-transfer-extra]
utp-expr.numeral-uexpr-rep-eq [uexpr-transfer-extra]
utp-expr.less-eq-uexpr.rep-eq [uexpr-transfer-extra]
Abs-uexpr-inverse [simplified, uexpr-transfer-extra]
Rep-uexpr-inverse [uexpr-transfer-extra]
```

Tactic Definition We have all ingredients now to define the fast transfer tactic as a single simplification step.

```
method fast-uexpr-transfer = (simp add: uexpr-transfer-laws uexpr-rep-eq-thms uexpr-transfer-extra)
```

7.4 Interpretation

The interpretation of record state spaces as products is done using the laws provided by the utility theory *Interp*. Note that this step can be suppressed by using the *no-interp* option.

```
method uexpr-interp-tac = (simp \ add: lens-interp-laws)?
```

7.5 User Tactics

In this section, we finally set-up the six user tactics: *pred-simp*, *rel-simp*, *pred-auto*, *rel-auto*, *pred-blast* and *rel-blast*. For this, we first define the proof strategies that are to be applied *after* the transfer steps.

```
method utp-simp-tac = (clarsimp)?
method utp-auto-tac = ((clarsimp)?; auto)
method utp-blast-tac = ((clarsimp)?; blast)
```

The ML file below provides ML constructor functions for tactics that process arguments suitable and invoke the generic methods *gen-pred-tac* and *gen-rel-tac* with suitable arguments.

```
ML-file utp-tactics.ML
```

Finally, we execute the relevant outer commands for method setup. Sadly, this cannot be done at the level of Eisbach since the latter does not provide a convenient mechanism to process symbolic flags as arguments. It may be worth to put in a feature request with the developers of the Eisbach tool.

```
 \begin{array}{l} \textbf{method-setup} \ pred\text{-}simp = \langle \\ (Scan.lift \ UTP\text{-}Tactics.scan\text{-}args) >> \\ (fn \ args => fn \ ctxt => \\ let \ val \ prove\text{-}tac = Basic\text{-}Tactics.utp\text{-}simp\text{-}tac \ in} \\ (UTP\text{-}Tactics.inst\text{-}gen\text{-}pred\text{-}tac \ args \ prove\text{-}tac \ ctxt}) \\ end) \end{array}
```

```
(Scan.lift\ UTP\text{-}Tactics.scan\text{-}args) >>
   (fn \ args => fn \ ctxt =>

Lifting Parser and Pretty Printer 8

```
theory utp-lift-parser
                       imports utp-expr-insts
               \mathbf{keywords}\ no\text{-}utp\text{-}lift:: thy\text{-}decl\text{-}block\ \mathbf{and}\ utp\text{-}lit\text{-}vars:: thy\text{-}decl\text{-}block\ \mathbf{and}\ utp\text{-}expr\text{-}vars:: thy\text{-}decl\text{-}block\ \mathbf{and}\ utp\text{-}vars:: thy\text{-}decl\text{-}block\ \mathbf{and}\ utp\text{-}expr\text{-}vars:: thy\text{-}decl\text{-}block\ \mathbf{and}\ utp\text{-}expr\text{-
and utp-lift-notation :: thy-decl-block
begin
```

8.1 Parser

Here, we derive a parser for UTP expressions that mimicks (and indeed reuses) the syntax of HOL expressions. It has two main features: (1) it lifts HOL functions into UTP expressions using the (|>) construct; and (2) it recognises when a free variable is a declared lens and treats it as a UTP variable, whilst lifting HOL variables. The parser therefore allows free mixing of HOL operators and lenses.

Sometimes it is necessary that operators are handled in a special way however. We, therefore, first create a mutable data structure to store the names of constants that should not be lifted, and arguments of those constants that should not be further processed.

```
ML
structure\ VarOption = Theory-Data
     (type T = bool
       val\ empty = false
       val\ extend = I
       val\ merge = (fn\ (x,\ y) => x\ orelse\ y));
structure\ NoLiftUTP =\ Theory	ext{-}Data
     (type \ T = int \ list \ Symtab.table
       val\ empty = Symtab.empty
       val\ extend = I
       val\ merge = Symtab.merge\ (K\ true));
val - =
     let fun nolift-const thy (n, opt) =
                 let\ val\ Const\ (c, \cdot) = Proof\ Context.\ read\ const\ \{proper = true,\ strict = false\}\ (Proof\ Context.\ init\ -global\ const\ (c, \cdot) = Proof\ Context.\ read\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = false)\ (Proof\ Context.\ init\ -global\ const\ (proper = true,\ strict = true,\ strict = false)\ (proof\ Context.\ init\ -global\ const\ (proper =
thy) n
                        in NoLiftUTP.map (Symtab.update (c, (map Value.parse-int opt))) thy end
     in
     Outer-Syntax.command @{command-keyword no-utp-lift} declare that certain constants should not be
        --| Parse.$$$))) [])
            >> (fn \ ns =>
                      Toplevel.theory
                      (fn \ thy => Library.foldl \ (fn \ (thy, n) => nolift-const \ thy \ n) \ (thy, ns))))
     end;
     Outer-Syntax.command @{command-keyword utp-lit-vars} parse free variables as literals in UTP ex-
```

(Scan.succeed (Toplevel.theory (VarOption.put false)));

 $Outer-Syntax.command \ @\{command-keyword\ utp-expr-vars\}\ parse\ free\ variables\ as\ expressions\ in\ UTP\ expressions$

```
(Scan. succeed\ (\textit{Toplevel.theory}\ (\textit{VarOption.put}\ true)));
```

The core UTP operators should not be lifted. Certain operators have arguments that also should not be processed further by expression lifting. For example, in a substitution update $\sigma(x \mapsto v)$, the lens x (i.e. the second argument) should not be lifted as its target is not an expression. Consequently, constants names in the command **no-utp-lift** can be accompanied by a list of numbers stating the arguments that should be not be further processed.

no-utp-lift

```
uexpr-appl uop (0) bop (0) trop (0) qtop (0) lit (0)
Groups.zero Groups.one plus uminus minus times divide
var (0) in-var (0) out-var (0) cond numeral (0)
```

Add a quotation device for expressions that explicitly stops the lifting parser.

```
abbreviation (input) quote-uexpr :: ('a, 's) uexpr \Rightarrow ('a, 's) uexpr (@(-) [999] 999) where quote-uexpr p \equiv p
```

```
no-utp-lift quote-uexpr (0)
```

The following function takes a parser, but not-yet type-checked term, and wherever it encounters an application, it inserts a UTP expression operator. Any operators that have been marked in the above structure will not be lifted. In addition, when it encounters a constant or free variable it will use the type system to determine whether is has a lens type. If it does, then it constructs a UTP variable expression; otherwise it constructs a literal.

FIXME: Actually, this test is a little too coarse for some situations. For example, when the lens is bound by a λ -abstraction the type data is not available, and so it will not necessarily be recognised as a lens. This could either be fixed by adding proper syntactic procedure for determining lenses, or else by using type inference wrt. the bound lambda term.

\mathbf{ML} (

9.1 Substitution definitions

Variable substitution, like unrestriction, will be characterised semantically using lenses and state-spaces. Effectively a substitution σ is simply a function on the state-space which can be applied to an expression e using the syntax $\sigma \dagger e$. We introduce a polymorphic constant that will be used to represent application of a substitution, and also a set of theorems to represent laws.

```
consts usubst :: 's \Rightarrow 'a \Rightarrow 'b \text{ (infixr } \dagger 80)
```

named-theorems usubst

A substitution is simply a transformation on the alphabet; it shows how variables should be mapped to different values. Most of the time these will be homogeneous functions but for flexibility we also allow some operations to be heterogeneous.

```
type-synonym ('\alpha,'\beta) psubst = ('\beta, '\alpha) uexpr
type-synonym '\alpha usubst = ('\alpha, '\alpha) uexpr
```

Application of a substitution simply applies the function σ to the state binding b before it is handed to e as an input. This effectively ensures all variables are updated in e.

```
lift-definition subst :: ('\alpha, '\beta) psubst \Rightarrow ('a, '\beta) uexpr \Rightarrow ('a, '\alpha) uexpr is \lambda \ \sigma \ e \ b. \ e \ (\sigma \ b).
```

adhoc-overloading

 $usubst\ subst$

Substitutions can be updated by associating variables with expressions. We thus create an additional polymorphic constant to represent updating the value of a variable to an expression in a substitution, where the variable is modelled by type 'v. This again allows us to support different notions of variables, such as deep variables, later.

We can also represent an arbitrary substitution as below.

```
lift-definition subst-nil :: ('\alpha, '\beta) psubst (nil_s) is \lambda s. undefined.
```

```
lift-definition subst-id :: '\alpha \ usubst \ (id_s) is \lambda s. \ s.
```

```
lift-definition subst-comp :: ('\beta, '\gamma) psubst \Rightarrow ('\alpha, '\beta) psubst \Rightarrow ('\alpha, '\gamma) psubst (infixl \circ_s 55) is (\circ).
```

```
\begin{array}{l} \textbf{lift-definition} \ inv\text{-}subst :: ('\alpha, '\beta) \ psubst \Rightarrow ('\beta, '\alpha) \ psubst \ (inv_s) \ \textbf{is} \ inv \ \textbf{.} \\ \textbf{lift-definition} \ inj\text{-}subst :: ('\alpha, '\beta) \ psubst \Rightarrow bool \ (inj_s) \ \textbf{is} \ inj \ \textbf{.} \\ \textbf{lift-definition} \ bij\text{-}subst :: ('\alpha, '\beta) \ psubst \Rightarrow bool \ (bij_s) \ \textbf{is} \ bij \ \textbf{.} \end{array}
```

```
declare inj-subst-def [uexpr-transfer-extra] declare bij-subst-def [uexpr-transfer-extra]
```

The following function takes a substitution form state-space α to β , a lens with source β and view "a", and an expression over α and returning a value of type "a, and produces an updated substitution. It does this by constructing a substitution function that takes state binding b, and updates the state first by applying the original substitution σ , and then updating the part of the state associated with lens x with expression evaluated in the context of b. This effectively means that x is now associated with expression v. We add this definition to our overloaded constant.

```
lift-definition subst-upd :: ('\alpha,'\beta) \ psubst \Rightarrow ('a \Longrightarrow '\beta) \Rightarrow ('a, '\alpha) \ uexpr \Rightarrow ('\alpha,'\beta) \ psubst is \lambda \ \sigma \ x \ v \ s. \ put_x \ (\sigma \ s) \ (v \ s).
```

The next function looks up the expression associated with a variable in a substitution by use of the get lens function.

```
lift-definition usubst-lookup :: ('\alpha, '\beta) psubst \Rightarrow ('a \Longrightarrow '\beta) \Rightarrow ('a, '\alpha) uexpr (\langle -\rangle_s) is \lambda \sigma x b. get<sub>x</sub> (\sigma b).
```

Substitutions also exhibit a natural notion of unrestriction which states that σ does not restrict x if application of σ to an arbitrary state ρ will not effect the valuation of x. Put another way, it requires that put and the substitution commute.

```
lift-definition unrest\text{-}usubst :: ('a \Longrightarrow '\alpha) \Rightarrow '\alpha \ usubst \Rightarrow bool
is \lambda \ x \ \sigma. (\forall \ \varrho \ v. \ \sigma \ (put_x \ \varrho \ v) = put_x \ (\sigma \ \varrho) \ v).
syntax
   -unrest-usubst :: salpha \Rightarrow logic \Rightarrow logic \Rightarrow logic (infix \sharp_s 20)
translations
   -unrest-usubst x p == CONST unrest-usubst x p
   \textit{-unrest-usubst} \ (\textit{-salphaset} \ (\textit{-salphamk} \ (x \ +_L \ y))) \ P \ <= \ \textit{-unrest-usubst} \ (x \ +_L \ y) \ P
```

Parallel substitutions allow us to divide the state space into three segments using two lens, A and B. They correspond to the part of the state that should be updated by the respective substitution. The two lenses should be independent. If any part of the state is not covered by either lenses then this area is left unchanged (framed).

```
lift-definition par-subst :: '\alpha usubst \Rightarrow ('a \Longrightarrow '\alpha) \Rightarrow ('b \Longrightarrow '\alpha) \Rightarrow '\alpha usubst \Rightarrow '\alpha usubst is
\lambda \ \sigma_1 \ A \ B \ \sigma_2. \ (\lambda \ s. \ (s \oplus_L \ (\sigma_1 \ s) \ on \ A) \oplus_L \ (\sigma_2 \ s) \ on \ B).
```

no-utp-lift subst-upd (1) subst usubst

9.2Syntax translations

We support two kinds of syntax for substitutions, one where we construct a substitution using a maplet-style syntax, with variables mapping to expressions. Such a constructed substitution can be applied to an expression. Alternatively, we support the more traditional notation, P[v/x], which also support multiple simultaneous substitutions. We have to use double square brackets as the single ones are already well used.

We set up non-terminals to represent a single substitution maplet, a sequence of maplets, a list of expressions, and a list of alphabets. The parser effectively uses subst-upd to construct substitutions from multiple variables.

nonterminal smaplet and smaplets and salphas

```
syntax
```

```
(-/\mapsto_s/-)
-smaplet :: [salpha, uexp] => smaplet
         :: smaplet => smaplets
-SMaplets :: [smaplet, smaplets] => smaplets (-,/-)
-SubstUpd :: ['m usubst, smaplets] => 'm usubst (-/'(-') [900,0] 900)
-Subst :: smaplets => logic
                                             ((1[-]))
-PSubst :: smaplets => logic
                                              ((1(|-|)))
-psubst :: [logic, svars, uexprs] \Rightarrow logic
          :: logic \Rightarrow uexprs \Rightarrow salphas \Rightarrow logic ((-\llbracket -'/-\rrbracket) [990,0,0] 991)
-uexp-l :: logic \Rightarrow uexp (- [64] 64)
-uexprs :: [uexp, uexprs] => uexprs (-,/-)
         :: uexp => uexprs (-)
-salphas :: [salpha, salphas] => salphas (-,/-)
         :: salpha => salphas (-)
-par-subst:: logic \Rightarrow salpha \Rightarrow salpha \Rightarrow logic \Rightarrow logic (-[-]-]_s - [100,0,0,101] \ 101)
```

translations

```
-SubstUpd \ m \ (-SMaplets \ xy \ ms)
                                   == -SubstUpd (-SubstUpd m xy) ms
-SubstUpd \ m \ (-smaplet \ x \ y)
                                 => CONST subst-upd m x U(y)
-SubstUpd \ m \ (-smaplet \ x \ y)
                                 <= CONST subst-upd m x y
                             == -SubstUpd id_s ms
-Subst ms
-Subst (-SMaplets ms1 ms2)
                                  <= -SubstUpd (-Subst ms1) ms2
```

```
 -PSubst \ ms = -Subst Upd \ nil_s \ ms \\ -PSubst \ (-SMaplets \ ms1 \ ms2) < = -Subst Upd \ (-PSubst \ ms1) \ ms2 \\ -SMaplets \ ms1 \ (-SMaplets \ ms2 \ ms3) < = -SMaplets \ (-SMaplets \ ms1 \ ms2) \ ms3 \\ -subst \ P \ es \ vs => CONST \ subst \ (-psubst \ id_s \ vs \ es) \ P \\ -psubst \ m \ (-salphas \ x \ xs) \ (-uexprs \ v \ vs) => -psubst \ (-psubst \ m \ x \ v) \ xs \ vs \\ -psubst \ m \ x \ v => CONST \ subst-upd \ m \ x \ v \\ -subst \ P \ v \ x <= CONST \ usubst \ (CONST \ subst-upd \ id_s \ x \ v) \ P \\ -subst \ P \ v \ x <= -subst \ P \ (-spvar \ x) \ v \\ -par-subst \ \sigma_1 \ A \ B \ \sigma_2 = CONST \ par-subst \ \sigma_1 \ A \ B \ \sigma_2 \\ -uexp-l \ e => e
```

Thus we can write things like $\sigma(x \mapsto_s v)$ to update a variable x in σ with expression v, $[x \mapsto_s e, y \mapsto_s f]$ to construct a substitution with two variables, and finally P[v/x], the traditional syntax.

We can now express deletion of a substitution maplet.

```
definition subst-del :: '\alpha usubst \Rightarrow ('a \Longrightarrow '\alpha) \Rightarrow '\alpha usubst (infix -_s 85) where subst-del \sigma x = \sigma(x \mapsto_s \& x)
```

9.3 Substitution Application Laws

We set up a simple substitution tactic that applies substitution and unrestriction laws

```
method subst-tac = (simp \ add: \ usubst \ unrest)?
```

assumes weak-lens x

Evaluation of a substitution expression involves application of the substitution to different variables. Thus we first prove laws for these cases. The simplest substitution, id, when applied to any variable x simply returns the variable expression, since id has no effect.

11 Alphabetised Predicates

```
theory utp-pred
imports
utp-expr-funcs
utp-subst
utp-meta-subst
```

```
utp-tactics
utp-lift-parser
begin
```

In this theory we begin to create an Isabelle version of the alphabetised predicate calculus that is described in Chapter 1 of the UTP book [22].

11.1 Predicate type and syntax

An alphabetised predicate is a simply a boolean valued expression.

```
type-synonym '\alpha upred = (bool, '\alpha) uexpr
```

translations

purge-notation

```
(type)'\alpha upred \le (type) (bool, '\alpha) uexpr
```

We want to remain as close as possible to the mathematical UTP syntax, but also want to be conservative with HOL. For this reason we chose not to steal syntax from HOL, but where possible use polymorphism to allow selection of the appropriate operator (UTP vs. HOL). Thus we will first remove the standard syntax for conjunction, disjunction, and negation, and replace these with adhoc overloaded definitions. We similarly use polymorphic constants for the other predicate calculus operators.

```
conj (infixr \land 35) and disj (infixr \lor 30) and Not (\neg - [40] 40)
```

```
utrue :: 'a (true)

ufalse :: 'a (false)

uconj :: 'a \Rightarrow 'a \Rightarrow 'a (infixr \wedge 35)

udisj :: 'a \Rightarrow 'a \Rightarrow 'a (infixr \wedge 30)

uimpl :: 'a \Rightarrow 'a \Rightarrow 'a (infixr \Rightarrow 25)

uiff :: 'a \Rightarrow 'a \Rightarrow 'a (infixr \Rightarrow 25)

unot :: 'a \Rightarrow 'a (\sigma - [40] 40)

uex :: ('a \Rightarrow '\alpha) \Rightarrow 'p \Rightarrow 'p

uall :: ('a \Rightarrow '\alpha) \Rightarrow 'p \Rightarrow 'p
```

adhoc-overloading

```
uconj conj and
udisj disj and
unot Not
```

```
abbreviation shEx :: ['\beta \Rightarrow' \alpha \ upred] \Rightarrow '\alpha \ upred where shEx \ P \equiv *Ex* \mid > uabs \ P
```

```
abbreviation shAll :: ['\beta \Rightarrow '\alpha \ upred] \Rightarrow '\alpha \ upred where shAll \ P \equiv \ll All \gg |> uabs \ P
```

We set up two versions of each of the quantifiers: uex / uall and shEx / shAll. The former pair allows quantification of UTP variables, whilst the latter allows quantification of HOL variables in concert with the literal expression constructor $\ll x \gg$. Both varieties will be needed at various points. Syntactically they are distinguished by a boldface quantifier for the HOL versions (achieved by the "bold" escape in Isabelle).

${f nonterminal}$ idt-list

```
syntax
  -idt-el :: idt \Rightarrow idt-list (-)

  \forall x < y \cdot P
                                        => \forall x \cdot \ll x \gg <_u y \Rightarrow P
```

11.2 Predicate operators

We chose to maximally reuse definitions and laws built into HOL. For this reason, when introducing the core operators we proceed by lifting operators from the polymorphic algebraic hierarchy of HOL. Thus the initial definitions take place in the context of type class instantiations. We first introduce our own class called *refine* that will add the refinement operator syntax to the HOL partial order class.

```
class refine = order  \begin{array}{l} \textbf{abbreviation} \ refineBy :: \ 'a :: refine \Rightarrow \ 'a \Rightarrow bool \ \ (\textbf{infix} \sqsubseteq 50) \ \textbf{where} \\ P \sqsubseteq Q \equiv less-eq \ Q \ P \end{array}
```

Since, on the whole, lattices in UTP are the opposite way up to the standard definitions in HOL, we syntactically invert the lattice operators. This is the one exception where we do steal HOL syntax, but I think it makes sense for UTP. Indeed we make this inversion for all of the lattice operators.

```
purge-notation Lattices.inf (infixl \Box 70) notation Lattices.inf (infixl \Box 70) purge-notation Lattices.sup (infixl \Box 65) notation Lattices.sup (infixl \Box 65) purge-notation Inf (\Box - [900] 900) notation Inf (\Box - [900] 900) purge-notation Sup (\Box - [900] 900) notation Sup (\Box - [900] 900)
```

```
purge-notation Orderings.bot (\perp)
notation Orderings.bot (\top)
purge-notation Orderings.top (\top)
notation Orderings.top (\bot)
purge-syntax
              :: pttrns \Rightarrow 'b \Rightarrow 'b
  -INF1

              :: pttrns \Rightarrow 'b \Rightarrow 'b \qquad ((3 \square -./ -) [0, 10] 10)
              :: pttrn \Rightarrow 'a \ set \Rightarrow 'b \Rightarrow 'b \ ((3 \square - \in -./ -) [0, 0, 10] \ 10)
  -SUP
We trivially instantiate our refinement class
instance uexpr :: (order, type) refine ..
— Configure transfer law for refinement for the fast relational tactics.
theorem upred-ref-iff [uexpr-transfer-laws]:
(P \sqsubseteq Q) = (\forall b. \ \llbracket Q \rrbracket_e \ b \longrightarrow \llbracket P \rrbracket_e \ b)
 apply (transfer)
 apply (clarsimp)
 done
Next we introduce the lattice operators, which is again done by lifting.
instantiation uexpr :: (lattice, type) lattice
begin
 lift-definition sup-uexpr :: ('a, 'b) uexpr \Rightarrow ('a, 'b) uexpr \Rightarrow ('a, 'b) uexpr
 is \lambda P Q A. Lattices. sup (P A) (Q A).
 lift-definition inf-uexpr :: ('a, 'b) uexpr \Rightarrow ('a, 'b) uexpr \Rightarrow ('a, 'b) uexpr
 is \lambda P \ Q \ A. Lattices.inf (P \ A) \ (Q \ A).
instance
 by (intro-classes) (transfer, auto)+
end
instantiation \ uexpr::(bounded-lattice, \ type) \ bounded-lattice
 lift-definition bot-uexpr :: ('a, 'b) uexpr is \lambda A. Orderings.bot.
 lift-definition top-uexpr :: ('a, 'b) uexpr is \lambda A. Orderings.top.
instance
 by (intro-classes) (transfer, auto)+
end
lemma top-uexpr-rep-eq [simp]:
  [Orderings.bot]_e b = False
 by (transfer, auto)
lemma bot-uexpr-rep-eq [simp]:
  [Orderings.top]_e b = True
  by (transfer, auto)
```

```
instance uexpr :: (distrib-lattice, type) distrib-lattice
by (intro-classes) (transfer, rule ext, auto simp add: sup-inf-distrib1)
```

Finally we show that predicates form a Boolean algebra (under the lattice operators), a complete lattice, a completely distribute lattice, and a complete boolean algebra. This equip us with a very complete theory for basic logical propositions.

```
instance uexpr :: (boolean-algebra, type) boolean-algebra
 apply (intro-classes, unfold uexpr-defs; transfer, rule ext)
   apply (simp-all add: sup-inf-distrib1 diff-eq)
 done
instantiation uexpr :: (complete-lattice, type) complete-lattice
begin
 lift-definition Inf-uexpr :: ('a, 'b) uexpr set \Rightarrow ('a, 'b) uexpr
 is \lambda PS A. INF P:PS. P(A).
 lift-definition Sup-uexpr :: ('a, 'b) uexpr set \Rightarrow ('a, 'b) uexpr
 is \lambda PS A. SUP P:PS. P(A).
instance
 by (intro-classes)
    (transfer, auto intro: INF-lower SUP-upper simp add: INF-greatest SUP-least)+
\mathbf{end}
instance uexpr::(complete-distrib-lattice, type) complete-distrib-lattice
 by (intro-classes; transfer; auto simp add: INF-SUP-set)
```

 $\mathbf{instance}\ uexpr\ ::\ (complete\ -boolean\ -algebra,\ type)\ complete\ -boolean\ -algebra\ \dots$

From the complete lattice, we can also define and give syntax for the fixed-point operators. Like the lattice operators, these are reversed in UTP.

syntax

```
-mu :: pttrn \Rightarrow logic \Rightarrow logic \ (\mu - \cdot - [0, 10] \ 10)

-nu :: pttrn \Rightarrow logic \Rightarrow logic \ (\nu - \cdot - [0, 10] \ 10)

notation gfp \ (\mu)

notation lfp \ (\nu)
```

translations

```
\nu \ X \cdot P == CONST \ lfp \ (\lambda \ X. \ P)

\mu \ X \cdot P == CONST \ gfp \ (\lambda \ X. \ P)
```

With the lattice operators defined, we can proceed to give definitions for the standard predicate operators in terms of them.

```
definition true-upred = (Orderings.top :: '\alpha upred) definition false-upred = (Orderings.bot :: '\alpha upred) definition conj-upred = (Lattices.inf :: '\alpha upred <math>\Rightarrow '\alpha upred \Rightarrow '\alpha upred) definition disj-upred = (Lattices.sup :: '\alpha upred <math>\Rightarrow '\alpha upred) definition not-upred = (uminus :: '\alpha upred <math>\Rightarrow '\alpha upred) definition diff-upred = (minus :: '\alpha upred <math>\Rightarrow '\alpha upred) definition Conj-upred :: '\alpha upred set <math>\Rightarrow '\alpha upred (\lambda - [900] 900) where A \equiv \coprod A abbreviation Disj-upred :: '\alpha upred set <math>\Rightarrow '\alpha upred (\lambda - [900] 900) where
```

```
\bigvee A \equiv \prod A
```

notation

```
conj-upred (infixr \wedge_p 35) and disj-upred (infixr \vee_p 30)
```

Perhaps slightly confusingly, the UTP infimum is the HOL supremum and vice-versa. This is because, again, in UTP the lattice is inverted due to the definition of refinement and a desire to have miracle at the top, and abort at the bottom.

```
lift-definition UINF :: ('a \Rightarrow '\alpha \ upred) \Rightarrow ('a \Rightarrow ('b::complete-lattice, '\alpha) \ uexpr) \Rightarrow ('b, '\alpha) \ uexpr is \lambda \ P \ F \ b. Sup \{ \llbracket F \ x \rrbracket_e \ b \mid x . \llbracket P \ x \rrbracket_e \ b \}.
```

lift-definition $USUP :: ('a \Rightarrow '\alpha \ upred) \Rightarrow ('a \Rightarrow ('b::complete-lattice, '\alpha) \ uexpr) \Rightarrow ('b, '\alpha) \ uexpr$ is $\lambda \ P \ F \ b$. Inf $\{ \llbracket F \ x \rrbracket_e b \mid x . \ \llbracket P \ x \rrbracket_e b \}$.

syntax

```
(\bigwedge - \cdot \cdot - [0, 10] \ 10)
(\bigsqcup - \cdot \cdot - [0, 10] \ 10)
-USup
               :: pttrn \Rightarrow logic \Rightarrow logic
               :: pttrn \Rightarrow logic \Rightarrow logic

12 Alphabet Manipulation

```
theory utp-alphabet
imports
utp-pred utp-usedby
begin
```

12.1 Preliminaries

Alphabets are simply types that characterise the state-space of an expression. Thus the Isabelle type system ensures that predicates cannot refer to variables not in the alphabet as this would be a type error. Often one would like to add or remove additional variables, for example if we wish to have a predicate which ranges only a smaller state-space, and then lift it into a predicate over a larger one. This is useful, for example, when dealing with relations which refer only to undashed variables (conditions) since we can use the type system to ensure well-formedness.

In this theory we will set up operators for extending and contracting and alphabet. We first set up a theorem attribute for alphabet laws and a tactic.

named-theorems alpha

```
method alpha-tac = (simp \ add: \ alpha \ unrest)?
```

12.2 Alphabet Extrusion

Alter an alphabet by application of a lens that demonstrates how the smaller alphabet (β) injects into the larger alphabet (α) . This changes the type of the expression so it is parametrised over the large alphabet. We do this by using the lens get function to extract the smaller state binding, and then apply this to the expression.

We call this "extrusion" rather than "extension" because if the extension lens is bijective then it does not extend the alphabet. Nevertheless, it does have an effect because the type will be different which can be useful when converting predicates with equivalent alphabets.

```
lift-definition aext:: ('a, '\beta) \ uexpr \Rightarrow ('\beta \Longrightarrow '\alpha) \Rightarrow ('a, '\alpha) \ uexpr \ (infixr \oplus_p \ 95) is \lambda \ P \ x \ b. \ P \ (get_x \ b).
```

update-uexpr-rep-eq-thms

no-utp-lift aext (1)

Next we prove some of the key laws. Extending an alphabet twice is equivalent to extending by the composition of the two lenses.

```
lemma aext-twice: (P \oplus_p a) \oplus_p b = P \oplus_p (a;_L b)
by (pred-auto)
```

The bijective Σ lens identifies the source and view types. Thus an alphabet extension using this has no effect.

```
lemma aext-id [simp]: P \oplus_p 1_L = P by (pred-auto)
```

Literals do not depend on any variables, and thus applying an alphabet extension only alters the predicate's type, and not its valuation.

```
lemma aext-lit [simp]: \ll v \gg \oplus_p \ a = \ll v \gg by (pred-auto)

 by (pred-auto)
lemma aext-divide [alpha]:
  (x / y) \oplus_p a = (x \oplus_p a) / (y \oplus_p a)
 by (pred-auto)
```

Extending a variable expression over x is equivalent to composing x with the alphabet, thus effectively yielding a variable whose source is the large alphabet.

```
lemma aext\text{-}var\ [alpha]:
var\ x\ \oplus_p\ a = var\ (x\ ;_L\ a)
by (pred\text{-}auto)

lemma aext\text{-}ulambda\ [alpha]: ((\lambda\ x\ \cdot\ P(x))\ \oplus_p\ a) = (\lambda\ x\ \cdot\ P(x)\ \oplus_p\ a)
by (pred\text{-}auto)

Alphabet extension is monotonic and continuous.

lemma aext\text{-}mono: P\sqsubseteq Q\Longrightarrow P\oplus_p\ a\sqsubseteq Q\oplus_p\ a
by (pred\text{-}auto)
```

lemma aext-cont [alpha]: vwb-lens $a \Longrightarrow (\bigcap A) \oplus_p a = (\bigcap P \in A. P \oplus_p a)$

If a variable is unrestricted in a predicate, then the extended variable is unrestricted in the predicate with an alphabet extension.

```
lemma unrest-aext [unrest]:

\llbracket mwb\text{-lens } a; x \sharp p \rrbracket \implies unrest (x ;_L a) (p \oplus_p a)
by (transfer, simp add: lens-comp-def)
```

If a given variable (or alphabet) b is independent of the extension lens a, that is, it is outside the original state-space of p, then it follows that once p is extended by a then b cannot be restricted.

```
lemma unrest-aext-indep [unrest]: a \bowtie b \Longrightarrow b \sharp (p \oplus_p a) by pred-auto
```

by (pred-simp)

12.3 Expression Alphabet Restriction

Restrict an alphabet by application of a lens that demonstrates how the smaller alphabet (β) injects into the larger alphabet (α) . Unlike extension, this operation can lose information if the expressions refers to variables in the larger alphabet.

```
lift-definition arestr :: ('a, '\alpha) \ uexpr \Rightarrow ('\beta \Longrightarrow '\alpha) \Rightarrow ('a, '\beta) \ uexpr \ (infixr \upharpoonright_e 90)
is \lambda P x b. P (create_x b).
no-utp-lift arestr (1)
update-uexpr-rep-eq-thms
lemma arestr-id [simp]: P \upharpoonright_e 1_L = P
 by (pred-auto)
lemma arestr-aext [simp]: mwb-lens a \Longrightarrow (P \oplus_p a) \upharpoonright_e a = P
 by (pred-auto)
If an expression's alphabet can be divided into two disjoint sections and the expression does
not depend on the second half then restricting the expression to the first half is loss-less.
lemma aext-arestr [alpha]:
 assumes mwb-lens a bij-lens (a +_L b) a \bowtie b b \sharp P
 shows (P \upharpoonright_e a) \oplus_p a = P
proof -

12.4 Predicate Alphabet Restriction

In order to restrict the variables of a predicate, we also need to existentially quantify away the other variables. We can't do this at the level of expressions, as quantifiers are not applicable here. Consequently, we need a specialised version of alphabet restriction for predicates. It both restricts the variables using quantification and then removes them from the alphabet type using expression restriction.

Lifting Expressions 13

mwb-lens $x \Longrightarrow (\sigma \oplus_s x) \upharpoonright_s x = \sigma$

```
theory utp-lift
 imports
   utp-alphabet
begin
```

Lifting definitions 13.1

We define operators for converting an expression to and from a relational state space with the help of alphabet extrusion and restriction. In general throughout Isabelle/UTP we adopt the

notation $\lceil P \rceil$ with some subscript to denote lifting an expression into a larger alphabet, and $\lfloor P \rfloor$ for dropping into a smaller alphabet.

The following two functions lift and drop an expression, respectively, whose alphabet is $'\alpha$, into a product alphabet $'\alpha \times '\beta$. This allows us to deal with expressions which refer only to undashed variables, and use the type-system to ensure this.

```
abbreviation lift-pre :: ('a, '\alpha) uexpr \Rightarrow ('a, '\alpha \times '\beta) uexpr ([-]<) where \lceil P \rceil_{<} \equiv P \oplus_{p} fst_{L} notation lift-pre (-\left\ [999] 999)
abbreviation drop-pre :: ('a, '\alpha \times '\beta) uexpr \Rightarrow ('a, '\alpha) uexpr ([-]<) where \lfloor P \rfloor_{<} \equiv P \upharpoonright_{e} fst_{L}
```

The following two functions lift and drop an expression, respectively, whose alphabet is β , into a product alphabet $\alpha \times \beta$. This allows us to deal with expressions which refer only to dashed variables.

```
abbreviation lift-post :: ('a, '\beta) uexpr \Rightarrow ('a, '\alpha \times '\beta) uexpr (\[ \cdot - \] \]) where [P]_> \equiv P \oplus_p snd_L
notation lift-post (-> [999] 999)
abbreviation drop-post :: ('a, '\alpha \times '\beta) uexpr \Rightarrow ('a, '\beta) uexpr (\[ \cdot - \] \]) where [P]_> \equiv P \upharpoonright_e snd_L
```

13.2 Lifting Laws

With the help of our alphabet laws, we can prove some intuitive laws about alphabet lifting. For example, lifting variables yields an unprimed or primed relational variable expression, respectively.

```
lemma lift-pre-var [simp]:

\lceil var \ x \rceil < = \$x

by (alpha-tac)

lemma lift-post-var [simp]:

\lceil var \ x \rceil > = \$x'

by (alpha-tac)
```

13.3 Substitution Laws

```
lemma pre-var-subst [usubst]: \sigma(\$x \mapsto_s \ll v \gg) \uparrow \lceil P \rceil_{<} = \sigma \uparrow \lceil P \llbracket \ll v \gg / \&x \rrbracket \rceil_{<} by (pred-simp)
```

13.4 Unrestriction laws

Crucially, the lifting operators allow us to demonstrate unrestriction properties. For example, we can show that no primed variable is restricted in an expression over only the first element of the state-space product type.

```
lemma unrest-dash-var-pre [unrest]:
fixes x :: ('a \Longrightarrow '\alpha)
shows x' \not\models [p]_{<}
by (pred-auto)
```

end

14.10 Refinement By Observation

Function to obtain the set of observations of a predicate **definition** obs-upred :: ' α upred \Rightarrow ' α set ($\llbracket - \rrbracket_o$)

```
where [upred-defs]: [\![P]\!]_o = \{b. \ [\![P]\!]_e b\}
lemma obs-upred-refine-iff:
P \sqsubseteq Q \longleftrightarrow [\![Q]\!]_o \subseteq [\![P]\!]_o
by (pred-auto)
```

A refinement can be demonstrated by considering only the observations of the predicates which are relevant, i.e. not unrestricted, for them. In other words, if the alphabet can be split into two disjoint segments, x and y, and neither predicate refers to y then only x need be considered when checking for observations.

```

15.3 Pretty Printer

The pretty printer infers when a HOL expression is actually a UTP expression by determing whether it contains operators like *bop*, *lit* etc. If so, it inserts the syntactic UTP quote defined above and then pushes these upwards through the expression syntax as far as possible, removing

expression operators along the way. In this way, lifted HOL expressions are printed exactly as the HOL expression with a quote around.

There are two phases to this implementation. Firstly, a collection of print translation functions for each of the combinators for functions, such as *uop* and *bop* insert a UTP quote for each subexpression that is not also headed by such a combinator. This is effectively trying to find "leaf nodes" in an expression. Secondly, a set of translation rules push the UTP quotes upwards, combining where necessary, to the highest possible level, removing the expression operators as they go.

We manifest the pretty printer through two commands that enable and disable it. Disabling allows us to inspect the syntactic structure of a term.

16 Alphabetised Relations

```
theory utp-rel
imports
utp-pred-laws
utp-healthy
utp-lift
utp-tactics
utp-lift-pretty
begin
```

An alphabetised relation is simply a predicate whose state-space is a product type. In this theory we construct the core operators of the relational calculus, and prove a libary of associated theorems, based on Chapters 2 and 5 of the UTP book [22].

16.1 Relational Alphabets

We set up convenient syntax to refer to the input and output parts of the alphabet, as is common in UTP. Since we are in a product space, these are simply the lenses fst_L and snd_L .

```
definition in\alpha :: ('\alpha \Longrightarrow '\alpha \times '\beta) where [lens\text{-}defs]: in\alpha = fst_L

definition out\alpha :: ('\beta \Longrightarrow '\alpha \times '\beta) where [lens\text{-}defs]: out\alpha = snd_L

lemma in\alpha\text{-}uvar [simp]: vwb\text{-}lens in\alpha
by (unfold\text{-}locales, auto simp add: in\alpha\text{-}def)

lemma out\alpha\text{-}uvar [simp]: vwb\text{-}lens out\alpha
by (unfold\text{-}locales, auto simp add: out\alpha\text{-}def)

lemma var\text{-}in\text{-}alpha [simp]: x ;_L in\alpha = in\text{-}var x
by (simp add: fst\text{-}lens\text{-}def in\alpha\text{-}def in\text{-}var\text{-}def)

lemma var\text{-}out\text{-}alpha [simp]: x ;_L out\alpha = out\text{-}var x
by (simp add: out\alpha\text{-}def out\text{-}var\text{-}def snd\text{-}lens\text{-}def)

lemma drop\text{-}pre\text{-}inv [simp]: [[out\alpha \sharp p]] \Longrightarrow [[p] < [var \to p]
by (pred\text{-}simp)
```

```
in\alpha \sharp_s \sigma \Longrightarrow \langle \sigma \rangle_s (in\text{-}var x) = \$x
  by (rel\text{-}simp, metis fstI)
lemma usubst-lookup-out-var-unrest [usubst]:
  out\alpha \sharp_s \sigma \Longrightarrow \langle \sigma \rangle_s (out\text{-}var x) = \$x'
  by (rel\text{-}simp, metis sndI)
lemma out-alpha-in-indep [simp]:
  out\alpha \bowtie in\text{-}var \ x \ in\text{-}var \ x \bowtie out\alpha
  by (simp-all add: in-var-def out \alpha-def lens-indep-def fst-lens-def snd-lens-def lens-comp-def)
lemma in-alpha-out-indep [simp]:
  in\alpha \bowtie out\text{-}var \ x \ out\text{-}var \ x \bowtie in\alpha
  by (simp-all add: in-var-def in\alpha-def lens-indep-def fst-lens-def lens-comp-def)
The following two functions lift a predicate substitution to a relational one.
abbreviation usubst-rel-lift :: '\alpha usubst \Rightarrow ('\alpha \times '\beta) usubst ([-]_s) where
[\sigma]_s \equiv \sigma \oplus_s in\alpha
abbreviation usubst-rel-drop :: ('\alpha \times '\alpha) usubst \Rightarrow '\alpha usubst (|-|_s) where
|\sigma|_s \equiv \sigma \upharpoonright_s in\alpha
no-utp-lift usubst-rel-lift
no-utp-lift usubst-rel-drop
The alphabet of a relation then consists wholly of the input and output portions.
```

16.2 Relational Types and Operators

by (simp add: fst-snd-id-lens in α -def lens-equiv-refl out α -def)

lemma alpha-in-out: $\Sigma \approx_L in\alpha +_L out\alpha$

We create type synonyms for conditions (which are simply predicates) – i.e. relations without dashed variables –, alphabetised relations where the input and output alphabet can be different, and finally homogeneous relations.

```
type-synonym '\alpha cond = '\alpha upred
type-synonym ('\alpha, '\beta) urel = ('\alpha × '\beta) upred
type-synonym '\alpha hrel = ('\alpha × '\alpha) upred
type-synonym ('\alpha, '\alpha) hexpr = ('\alpha, '\alpha × '\alpha) uexpr
translations
```

```
(type) ('\alpha, '\beta) urel \le (type) ('\alpha \times '\beta) upred
```

We set up some overloaded constants for sequential composition and the identity in case we want to overload their definitions later.

```
consts
```

```
useq :: 'a \Rightarrow 'b \Rightarrow 'c (infixr ;; 61)

uassigns :: ('a, 'b) psubst \Rightarrow 'c (\langle -\rangle_a)

uskip :: 'a (II)
```

We define a specialised version of the conditional where the condition can refer only to undashed variables, as is usually the case in programs, but not universally in UTP models. We implement this by lifting the condition predicate into the relational state-space with construction $b^{<}$.

```
definition lift-rcond (\lceil - \rceil_{\leftarrow}) where [upred-defs]: \lceil b \rceil_{\leftarrow} = \lceil b \rceil_{<}
```

abbreviation

```
rcond :: ('\alpha, '\beta) urel \Rightarrow '\alpha cond \Rightarrow ('\alpha, '\beta) urel \Rightarrow ('\alpha, '\beta) urel \Rightarrow ((3- \triangleleft - \triangleright_r/ -) [52,0,53] 52) where (P \triangleleft b \triangleright_r Q) \equiv (P \triangleleft \lceil b \rceil_{\leftarrow} \triangleright Q)
```

Sequential composition is heterogeneous, and simply requires that the output alphabet of the first matches then input alphabet of the second. We define it by lifting HOL's built-in relational composition operator (O). Since this returns a set, the definition states that the state binding b is an element of this set.

```
lift-definition seqr::('\alpha, '\beta) \ urel \Rightarrow ('\beta, '\gamma) \ urel \Rightarrow ('\alpha \times '\gamma) \ upred is \lambda \ P \ Q \ b. \ b \in (\{p. \ P \ p\} \ O \ \{q. \ Q \ q\}).
```

adhoc-overloading

useq seqr

We also set up a homogeneous sequential composition operator, and versions of U(true) and U(false) that are explicitly typed by a homogeneous alphabet.

```
abbreviation seqh:: '\alpha \ hrel \Rightarrow '\alpha \ hrel \Rightarrow '\alpha \ hrel \ (infixr:_{h} \ 61) where seqh \ P \ Q \equiv (P:_{h} \ Q)
```

```
abbreviation truer :: '\alpha \ hrel \ (true_h) where truer \equiv true
```

```
abbreviation falser :: '\alpha \ hrel \ (false_h) where falser \equiv false
```

We define the relational converse operator as an alphabet extrusion on the bijective lens $swap_L$ that swaps the elements of the product state-space.

```
abbreviation conv-r :: ('a, '\alpha \times '\beta) uexpr \Rightarrow ('a, '\beta \times '\alpha) uexpr (- [999] 999) where conv-r e \equiv e \oplus_p swap_L
```

Assignment is defined using substitutions, where latter defines what each variable should map to. This approach, which is originally due to Back [3], permits more general assignment expressions. The definition of the operator identifies the after state binding, b', with the substitution function applied to the before state binding b.

```
lift-definition assigns-r:('\alpha,'\beta) psubst \Rightarrow ('\alpha,'\beta) urel is \lambda \sigma (b, b'). b' = \sigma(b).
```

adhoc-overloading

uassigns assigns-r

Relational identity, or skip, is then simply an assignment with the identity substitution: it simply identifies all variables.

```
definition skip-r :: '\alpha \ hrel \ \mathbf{where} [urel-defs]: skip-r = assigns-r \ id_s
```

adhoc-overloading

 $uskip\ skip\ -r$

Non-deterministic assignment, also known as "choose", assigns an arbitrarily chosen value to the given variable

```
definition nd-assign :: ('a \Longrightarrow '\alpha) \Rightarrow '\alpha hrel where [urel-defs]: nd-assign x = (\bigcap v \cdot assigns r [x \mapsto_s \ll v \gg])
```

We set up iterated sequential composition which iterates an indexed predicate over the elements of a list.

```
definition seqr-iter :: 'a list \Rightarrow ('a \Rightarrow 'b hrel) \Rightarrow 'b hrel where [urel-defs]: seqr-iter xs P = foldr (\lambda i Q. P(i) ;; Q) xs II
```

A singleton assignment simply applies a singleton substitution function, and similarly for a double assignment.

```
abbreviation assign-r::('t\Longrightarrow'\alpha)\Rightarrow('t,\ '\alpha)\ uexpr\Rightarrow'\alpha\ hrel where assign-r\ x\ v\equiv\langle[x\mapsto_s\ v]\rangle_a
```

```
abbreviation assign-2-r ::
```

```
('t1 \Longrightarrow '\alpha) \Rightarrow ('t2 \Longrightarrow '\alpha) \Rightarrow ('t1, '\alpha) \ uexpr \Rightarrow ('t2, '\alpha) \ uexpr \Rightarrow '\alpha \ hrel
where assign-2-r x y u v \equiv assigns-r [x \mapsto_s u, y \mapsto_s v]
```

We also define the alphabetised skip operator that identifies all input and output variables in the given alphabet lens. All other variables are unrestricted. We also set up syntax for it.

```
definition skip\text{-}ra :: ('\beta, '\alpha) \ lens \Rightarrow '\alpha \ hrel \ \mathbf{where} [urel\text{-}defs]: skip\text{-}ra \ v = (\$v' =_u \$v)
```

Similarly, we define the alphabetised assignment operator.

```
definition assigns-ra :: '\alpha usubst \Rightarrow ('\beta, '\alpha) lens \Rightarrow '\alpha hrel (\langle - \rangle_-) where \langle \sigma \rangle_a = (\lceil \sigma \rceil_s \dagger skip\text{-ra } a)
```

Assumptions (c^{\top}) and assertions (c_{\perp}) are encoded as conditionals. An assumption behaves like skip if the condition is true, and otherwise behaves like U(false) (miracle). An assertion is the same, but yields U(true), which is an abort. They are the same as tests, as in Kleene Algebra with Tests [24, 1] (KAT), which embeds a Boolean algebra into a Kleene algebra to represent conditions.

```
definition rassume :: '\alpha upred \Rightarrow '\alpha hrel ([-]^{\top}) where [urel-defs]: rassume c = II \triangleleft c \triangleright_r false
```

notation rassume (?[-])

utp-lift-notation rassume (0)

```
definition rassert :: '\alpha upred \Rightarrow '\alpha hrel ({-}_{\perp}) where [urel-defs]: rassert c = II \triangleleft c \triangleright_r true
```

```
utp-lift-notation rassert (\theta)
```

We also encode "naked" guarded commands [8, ?] by composing an assumption with a relation.

```
definition rgcmd :: 'a upred \Rightarrow 'a hrel \Rightarrow 'a hrel (-\longrightarrow_r - [55, 56] 55) where [urel-defs]: rgcmd b P = (rassume b ;; P)
```

```
utp-lift-notation rgcmd (\theta)
```

We define two variants of while loops based on strongest and weakest fixed points. The former is U(false) for an infinite loop, and the latter is U(true).

```
definition while-top :: '\alpha cond \Rightarrow '\alpha hrel \Rightarrow '\alpha hrel (while ^{\top} - do - od) where [urel-defs]: while-top b \ P = (\nu \ X \cdot (P \ ;; \ X) \triangleleft b \triangleright_r II)
```

```
notation while-top (while - do - od)
```

utp-lift-notation while-top (0)

```
definition while-bot :: '\alpha cond \Rightarrow '\alpha hrel \Rightarrow '\alpha hrel (while _{\perp} - do - od) where [urel-defs]: while-bot b P = (\mu \ X \cdot (P \ ;; \ X) \triangleleft b \triangleright_r II)
```

utp-lift-notation while-bot (θ)

While loops with invariant decoration (cf. [1]) – partial correctness.

```
definition while-inv :: '\alpha cond \Rightarrow '\alpha cond \Rightarrow '\alpha hrel \Rightarrow '\alpha hrel (while - invr - do - od) where [urel-defs]: while-inv b p S = while-top b S
```

```
utp-lift-notation while-inv (0\ 1)
```

While loops with invariant decoration – total correctness.

```
definition while-inv-bot :: '\alpha cond \Rightarrow '\alpha cond \Rightarrow '\alpha hrel \Rightarrow '\alpha hrel (while _{\perp} - invr - do - od 71) where [urel-defs]: while-inv-bot b p S = while-bot b S
```

```
utp-lift-notation while-inv-bot (0 1)
```

While loops with invariant and variant decorations – total correctness.

 $\textbf{definition} \ \textit{while-vrt} ::$

```
'\alpha cond \Rightarrow '\alpha cond \Rightarrow (nat, '\alpha) uexpr \Rightarrow '\alpha hrel \Rightarrow '\alpha hrel (while - invr - vrt - do - od) where [urel-defs]: while-vrt b p v S = while-bot b S
```

utp-lift-notation while-vrt (0 1 2)

translations

```
 \begin{split} ?[b] <&= ?[U(b)] \\ \{b\}_\bot <&= \{U(b)\}_\bot \\ while \ b \ do \ P \ od <&= while \ U(b) \ do \ P \ od \end{split}
```

We implement a poor man's version of alphabet restriction that hides a variable within a relation.

```
definition rel-var-res :: '\alpha hrel \Rightarrow ('a \Longrightarrow '\alpha) \Rightarrow '\alpha hrel (infix \upharpoonright_{\alpha} 80) where [urel-defs]: P \upharpoonright_{\alpha} x = (\exists \$x \cdot \exists \$x' \cdot P)
```

Alphabet extension and restriction add additional variables by the given lens in both their primed and unprimed versions.

```
definition rel-aext :: '\beta hrel \Rightarrow ('\beta \Longrightarrow '\alpha) \Rightarrow '\alpha hrel where [upred-defs]: rel-aext P a = P \oplus_p (a \times_L a)
```

```
definition rel-ares :: '\alpha hrel \Rightarrow ('\beta \Longrightarrow '\alpha) \Rightarrow '\beta hrel where [upred-defs]: rel-ares P a = (P \upharpoonright_p (a \times a))
```

We next describe frames and antiframes with the help of lenses. A frame states that P defines how variables in a changed, and all those outside of a remain the same. An antiframe describes the converse: all variables outside a are specified by P, and all those in remain the same. For more information please see [25].

```
definition frame :: ('a \Longrightarrow '\alpha) \Rightarrow '\alpha \ hrel \Rightarrow '\alpha \ hrel \ where [urel-defs]: frame a <math>P = (P \land \$\mathbf{v}' =_u \$\mathbf{v} \oplus \$\mathbf{v}' \ on \ \&a)
```

```
definition antiframe :: ('a \Longrightarrow '\alpha) \Rightarrow '\alpha \ hrel \Rightarrow '\alpha \ hrel where
[urel-defs]: antiframe a P = (P \land \$\mathbf{v}' =_u \$\mathbf{v}' \oplus \$\mathbf{v} \text{ on } \& a)
```

Frame extension combines alphabet extension with the frame operator to both add additional variables and then frame those.

```
definition rel-frext :: ('\beta \Longrightarrow '\alpha) \Rightarrow '\beta \ hrel \Rightarrow '\alpha \ hrel where
[upred-defs]: rel-frext\ a\ P = frame\ a\ (rel-aext\ P\ a)
```

The nameset operator can be used to hide a portion of the after-state that lies outside the lens a. It can be useful to partition a relation's variables in order to conjoin it with another relation.

```
definition nameset :: ('a \Longrightarrow '\alpha) \Rightarrow '\alpha \ hrel \Rightarrow '\alpha \ hrel \ where
[urel-defs]: nameset a P = (P \upharpoonright_v \{\$\mathbf{v},\$a'\})
```

```

The following code sets up pretty-printing for homogeneous relational expressions. We cannot do this via the "translations" command as we only want the rule to apply when the input and output alphabet types are the same. The code has to deconstruct a $('a, '\alpha)$ uexpr type, determine that it is relational (product alphabet), and then checks if the types alpha and beta are the same. If they are, the type is printed as a hexpr. Otherwise, we have no match. We then set up a regular translation for the hrel type that uses this.

```
print-translation ( let fun tr' ctx [ a , Const (@\{type\text{-syntax prod}\},-) $ alpha $ beta ] = if (alpha = beta) then Syntax.const @\{type\text{-syntax hexpr}\} $ a $ alpha else raise Match; in [(@\{type\text{-syntax uexpr}\},tr')] end } translations (type) '\alpha hrel <= (type) (bool, '\alpha) hexpr
```

16.4 Relation Properties

We describe some properties of relations, including functional and injective relations. We also provide operators for extracting the domain and range of a UTP relation.

```
definition ufunctional :: ('a, 'b) urel \Rightarrow bool where [urel-defs]: ufunctional R \longleftrightarrow II \sqsubseteq R^-;; R definition uinj :: ('a, 'b) urel \Rightarrow bool where [urel-defs]: uinj R \longleftrightarrow II \sqsubseteq R;; R^- definition Pre :: ('\alpha, '\beta) \ urel \Rightarrow '\alpha \ upred where [upred-defs]: Pre P = [\exists \ \mathbf{v}' \cdot P]_{<} definition Post :: ('\alpha, '\beta) \ urel \Rightarrow '\beta \ upred where [upred-defs]: Post P = [\exists \ \mathbf{v} \cdot P]_{>}
```

```
no-utp-lift Pre Post
```

20 UTP Theories

```
theory utp-theory imports utp-rel-laws begin
```

Here, we mechanise a representation of UTP theories using locales [4]. We also link them to the HOL-Algebra library [5], which allows us to import properties from complete lattices and Galois connections.

20.1 Complete lattice of predicates

```
definition upred-lattice :: ('\alpha upred) gorder (\mathcal{P}) where upred-lattice = (| carrier = UNIV, eq = (=), le = (\sqsubseteq) |
```

 \mathcal{P} is the complete lattice of alphabetised predicates. All other theories will be defined relative to it.

```
interpretation upred-lattice: complete-lattice \mathcal{P}
proof (unfold-locales, simp-all add: upred-lattice-def)
 \mathbf{fix} \ A :: '\alpha \ upred \ set
 show \exists s. is-lub (|carrier = UNIV, eq = (=), le = (\sqsubseteq)) s A
   apply (rule-tac \ x= \bigsqcup A \ in \ exI)
   apply (rule least-UpperI)
      apply (auto intro: Inf-greatest simp add: Inf-lower Upper-def)
 show \exists i. is-glb (|carrier = UNIV, eq = (=), le = (\sqsubseteq)) i A
   apply (rule greatest-LowerI)
      apply (auto intro: Sup-least simp add: Sup-upper Lower-def)
   done
qed
lemma upred-weak-complete-lattice [simp]: weak-complete-lattice \mathcal{P}
 by (simp add: upred-lattice.weak.weak-complete-lattice-axioms)
lemma upred-lattice-eq [simp]:
 (.=_{\mathcal{D}}) = (=)
 by (simp add: upred-lattice-def)
lemma upred-lattice-le [simp]:

lemma mono-Monotone-utp-order:
  mono\ f \Longrightarrow Monotone\ (utp-order\ T)\ f
 apply (auto simp add: isotone-def)
  apply (metis partial-order-def utp-partial-order)
 apply (metis monoD)
 done
lemma isotone-utp-orderI: Monotonic H \Longrightarrow isotone (utp-order X) (utp-order Y) H
  by (auto simp add: mono-def isotone-def utp-weak-partial-order)
lemma Mono-utp-orderI:
  \llbracket \land P Q. \rrbracket P \sqsubseteq Q; P \text{ is } H; Q \text{ is } H \rrbracket \Longrightarrow F(P) \sqsubseteq F(Q) \rrbracket \Longrightarrow Mono_{utn-order} H F
 by (auto simp add: isotone-def utp-weak-partial-order)
The UTP order can equivalently be characterised as the fixed point lattice, fpl.
lemma utp-order-fpl: utp-order H = fpl \mathcal{P} H
 by (auto simp add: utp-order-def upred-lattice-def fps-def Healthy-def)
```

20.3 UTP theory hierarchy

We next define a hierarchy of locales that characterise different classes of UTP theory. Minimally we require that a UTP theory's healthiness condition is idempotent.

```
locale utp-theory = fixes hcond :: '\alpha \ hrel \Rightarrow '\alpha \ hrel (\mathcal{H})
```

```
assumes HCond-Idem: \mathcal{H}(\mathcal{H}(P)) = \mathcal{H}(P)
begin
 abbreviation thy-order :: '\alpha hrel gorder where
  thy-order \equiv utp-order \mathcal{H}
 lemma HCond-Idempotent [closure,intro]: Idempotent \mathcal{H}
   by (simp add: Idempotent-def HCond-Idem)
 sublocale utp-po: partial-order utp-order \mathcal{H}
   by (unfold-locales, simp-all add: utp-order-def)
We need to remove some transitivity rules to stop them being applied in calculations
 declare utp-po.trans [trans del]
end
locale \ utp-theory-lattice = utp-theory +
 assumes uthy-lattice: complete-lattice (utp-order \mathcal{H})
begin
sublocale complete-lattice utp-order \mathcal{H}
 by (simp add: uthy-lattice)
declare top-closed [simp del]
declare bottom-closed [simp del]
The healthiness conditions of a UTP theory lattice form a complete lattice, and allows us to
make use of complete lattice results from HOL-Algebra [5], such as the Knaster-Tarski theorem.
We can also retrieve lattice operators as below.
abbreviation utp-top (\top)
where utp-top \equiv top (utp-order \mathcal{H})
abbreviation utp-bottom (\bot)
where utp-bottom \equiv bottom (utp-order \mathcal{H})
abbreviation utp-join (infixl \sqcup 65) where
utp-join \equiv join (utp-order \mathcal{H})
abbreviation utp-meet (infixl \sqcap 70) where
utp\text{-}meet \equiv meet \ (utp\text{-}order \ \mathcal{H})
abbreviation utp-sup (\bigsqcup - [90] 90) where
utp\text{-}sup \equiv Lattice.sup (utp\text{-}order \mathcal{H})
abbreviation utp-inf (\square - [90] 90) where
utp-inf \equiv Lattice.inf (utp-order \mathcal{H})
abbreviation utp-gfp(\nu) where
utp-gfp \equiv GREATEST-FP (utp-order \mathcal{H})
abbreviation utp-lfp (\mu) where
utp-lfp \equiv LEAST-FP (utp-order \mathcal{H})
end
```

```
syntax
  -tmu :: logic \Rightarrow pttrn \Rightarrow logic \Rightarrow logic (\mu_1 - \cdot - [0, 10] 10)

26 State Variable Declaration Parser

```
theory utp-state-parser imports utp-blocks begin
```

This theory sets up a parser for state blocks, as an alternative way of providing lenses to a predicate. A program with local variables can be represented by a predicate indexed by a tuple of lenses, where each lens represents a variable. These lenses must then be supplied with respect to a suitable state space. Instead of creating a type to represent this alphabet, we can create a product type for the state space, with an entry for each variable. Then each variable becomes a composition of the fst_L and snd_L lenses to index the correct position in the variable vector. We first creation a vacuous definition that will mark when an indexed predicate denotes a state block.

```
definition state-block :: ('v \Rightarrow 'p) \Rightarrow 'v \Rightarrow 'p where [upred-defs]: state-block f x = f x
```

We declare a number of syntax translations to produce lens and product types, to obtain a type for the overall state space, to construct a tuple that denotes the lens vector parameter, to construct the vector itself, and finally to construct the state declaration.

```

30 Concurrent Programming

```
theory utp-concurrency
imports
utp-hoare
utp-rel
utp-tactics
utp-theory
begin
```

In this theory we describe the UTP scheme for concurrency, parallel-by-merge, which provides a general parallel operator parametrised by a "merge predicate" that explains how to merge the after states of the composed predicates. It can thus be applied to many languages and

concurrency schemes, with this theory providing a number of generic laws. The operator is explained in more detail in Chapter 7 of the UTP book [22].

30.1 Variable Renamings

In parallel-by-merge constructions, a merge predicate defines the behaviour following execution of of parallel processes, $P \parallel Q$, as a relation that merges the output of P and Q. In order to achieve this we need to separate the variable values output from P and Q, and in addition the variable values before execution. The following three constructs do these separations. The initial state-space before execution is ' α , the final state-space after the first parallel process is ' β_0 , and the final state-space for the second is ' β_1 . These three functions lift variables on these three state-spaces, respectively.

```
alphabet ('\alpha, '\beta_0, '\beta_1) \ mrg = mrg\text{-}prior :: '\alpha 
 mrg\text{-}left :: '\beta_0 
 mrg\text{-}right :: '\beta_1
```

We set up syntax for the three variable classes.

syntax

```
-svarprior :: svid (<)
-svarl :: svid (0)
-svarr :: svid (1)
```

translations

```
\begin{array}{lll} -svarprior & == CONST \ mrg\text{-}prior \\ -svarl & == CONST \ mrg\text{-}left \\ -svarr & == CONST \ mrg\text{-}right \end{array}
```

30.2 Merge Predicates

A merge predicate is a relation whose input has three parts: the prior variables, the output variables of the left predicate, and the output of the right predicate.

```
type-synonym '\alpha merge = (('\alpha, '\alpha, '\alpha) mrg, '\alpha) urel
```

skip is the merge predicate which ignores the output of both parallel predicates

```
definition skip_m :: '\alpha \ merge \ \mathbf{where} [upred\text{-}defs]: skip_m = (\$\mathbf{v}' =_u \$ <: \mathbf{v})
```

swap is a predicate that the swaps the left and right indices; it is used to specify commutativity of the parallel operator

```
definition swap_m :: (('\alpha, '\beta, '\beta) \ mrg) \ hrel \ \mathbf{where} [upred\text{-}defs]: swap_m = (\theta:\mathbf{v}, 1:\mathbf{v}) := (\&1:\mathbf{v}, \&\theta:\mathbf{v})
```

A symmetric merge is one for which swapping the order of the merged concurrent predicates has no effect. We represent this by the following healthiness condition that states that $swap_m$ is a left-unit.

```
abbreviation SymMerge :: '\alpha \ merge \Rightarrow '\alpha \ merge \ \mathbf{where} SymMerge(M) \equiv (swap_m \ ; \ M)
```

30.3 Separating Simulations

U0 and U1 are relations modify the variables of the input state-space such that they become indexed with 0 and 1, respectively.

```
definition U0 :: ('\beta_0, ('\alpha, '\beta_0, '\beta_1) \ mrg) \ urel \ where
[upred-defs]: U0 = (\$0:\mathbf{v}' =_u \$\mathbf{v})
definition U1 :: ('\beta_1, ('\alpha, '\beta_0, '\beta_1) mrg) urel where
[upred-defs]: U1 = (\$1:\mathbf{v}' =_u \$\mathbf{v})
lemma U0-swap: (U0 ;; swap_m) = U1
 by (rel-auto)
lemma U1-swap: (U1 ;; swap_m) = U0
 by (rel-auto)
As shown below, separating simulations can also be expressed using the following two alphabet
extrusions
definition U0\alpha where [upred-defs]: U0\alpha = (1_L \times_L mrg\text{-left})
definition U1\alpha where [upred-defs]: U1\alpha = (1_L \times_L mrg\text{-}right)
We then create the following intuitive syntax for separating simulations.
abbreviation U0-alpha-lift ([-]_0) where [P]_0 \equiv P \oplus_p U0\alpha
abbreviation U1-alpha-lift ([-]_1) where [P]_1 \equiv P \oplus_p U1\alpha
[P]_0 is predicate P where all variables are indexed by 0, and [P]_1 is where all variables are
indexed by 1. We can thus equivalently express separating simulations using alphabet extrusion.

  by (simp add: U1\alpha-def alpha-out-var id-wb-lens out-var-prod-lens)
```

30.4 Associative Merges

Associativity of a merge means that if we construct a three way merge from a two way merge and then rotate the three inputs of the merge to the left, then we get exactly the same three way merge back.

We first construct the operator that constructs the three way merge by effectively wiring up the two way merge in an appropriate way.

```
definition Three WayMerge :: '\alpha merge \Rightarrow (('\alpha, '\alpha, ('\alpha, '\alpha, ('\alpha, '\alpha) mrg) mrg, '\alpha) urel (M3'(-')) where [upred-defs]: Three WayMerge M = ((\$0:\mathbf{v}' =_u \$0:\mathbf{v} \land \$1:\mathbf{v}' =_u \$1:0:\mathbf{v} \land \$<:\mathbf{v}' =_u \$<:\mathbf{v}) ;; M ;; U0 \land \$1:\mathbf{v}' =_u \$1:1:\mathbf{v} \land \$<:\mathbf{v}' =_u \$<:\mathbf{v}) ;; M
```

The next definition rotates the inputs to a three way merge to the left one place.

```
abbreviation rotate_m where rotate_m \equiv (\theta : \mathbf{v}, 1 : \theta : \mathbf{v}, 1 : 1 : \mathbf{v}) := (\&1 : \theta : \mathbf{v}, \&1 : 1 : \mathbf{v}, \&\theta : \mathbf{v})
```

Finally, a merge is associative if rotating the inputs does not effect the output.

```
definition AssocMerge :: '\alpha merge \Rightarrow bool where [upred-defs]: AssocMerge M = (rotate_m ;; \mathbf{M}\beta(M) = \mathbf{M}\beta(M))
```

30.5 Parallel Operators

We implement the following useful abbreviation for separating of two parallel processes and copying of the before variables, all to act as input to the merge predicate.

```
abbreviation par-sep (infixr \parallel_s 85) where P \parallel_s Q \equiv (P ;; U\theta) \land (Q ;; U1) \land \$<' =_u \$v
```

The following implementation of parallel by merge is less general than the book version, in that it does not properly partition the alphabet into two disjoint segments. We could actually achieve this specifying lenses into the larger alphabet, but this would complicate the definition of programs. May reconsider later.

definition

```
\begin{array}{l} par-by\text{-}merge :: ('\alpha, \ '\beta) \ urel \Rightarrow (('\alpha, \ '\beta, \ '\gamma) \ mrg, \ '\delta) \ urel \Rightarrow ('\alpha, \ '\gamma) \ urel \Rightarrow ('\alpha, \ '\delta) \ urel \\ (-\parallel_- - [85, 0, 86] \ 85) \\ \textbf{where} \ [upred\text{-}defs]: \ P \parallel_M \ Q = (P \parallel_s \ Q \ ;; \ M) \end{array}
```

lemma par-by-merge-alt-def: $P \parallel_M Q = (\lceil P \rceil_0 \land \lceil Q \rceil_1 \land \$ < : \mathbf{v'} =_u \$ \mathbf{v}) ;; M$ **by** (simp add: par-by-merge-def U0-as-alpha U1-as-alpha)

```
lemma shEx-pbm-left: ((\exists x \cdot P x) \parallel_M Q) = (\exists x \cdot (P x \parallel_M Q)) by (rel-auto)
```

```
lemma shEx-pbm-right: (P \parallel_M (\exists \ x \cdot Q \ x)) = (\exists \ x \cdot (P \parallel_M Q \ x)) by (rel-auto)
```

30.6 Unrestriction Laws

```

30.7 Substitution laws

Substitution is a little tricky because when we push the expression through the composition operator the alphabet of the expression must also change. Consequently for now we only support literal substitution, though this could be generalised with suitable alphabet coercisions. We need quite a number of variants to support this which are below.

```
 \begin{split} &\mathbf{lemma}\ \ U0\text{-}seq\text{-}subst\text{: } (P\ ;;\ U0)\llbracket \ll v \gg /\$0\text{:}x'\rrbracket = (P\llbracket \ll v \gg /\$x'\rrbracket\ ;;\ U0) \\ &\mathbf{by}\ (rel\text{-}auto) \end{split}   \begin{aligned} &\mathbf{lemma}\ \ U1\text{-}seq\text{-}subst\text{: } (P\ ;;\ U1)\llbracket \ll v \gg /\$1\text{:}x'\rrbracket = (P\llbracket \ll v \gg /\$x'\rrbracket\ ;;\ U1) \\ &\mathbf{by}\ (rel\text{-}auto) \end{aligned}   \begin{aligned} &\mathbf{lemma}\ \ lit\text{-}pbm\text{-}subst\ [usubst]\text{:} \\ &\mathbf{fixes}\ \ x::\ (-\Longrightarrow '\alpha) \\ &\mathbf{shows} \\ &\bigwedge\ P\ Q\ M\ \sigma.\ \sigma(\$x\mapsto_s \ll v \gg)\ \dagger\ (P\ \|_M\ Q) = \sigma\ \dagger\ ((P\llbracket \ll v \gg /\$x\rrbracket))\ \|_{M\llbracket \ll v \gg /\$ <:x\rrbracket}\ (Q\llbracket \ll v \gg /\$x\rrbracket)) \end{aligned}
```

```

33 Overloaded Expression Constructs

```
theory utp-expr-ovld imports utp begin
```

33.1 Overloadable Constants

For convenience, we often want to utilise the same expression syntax for multiple constructs. This can be achieved using ad-hoc overloading. We create a number of polymorphic constants and then overload their definitions using appropriate implementations. In order for this to work, each collection must have its own unique type. Thus we do not use the HOL map type directly, but rather our own partial function type, for example.

consts

```
Empty elements, for example empty set, nil list, 0...
uempty
— Function application, map application, list application...
             :: 'f \Rightarrow 'k \Rightarrow 'v
uapply
— Overriding
uovrd
            :: 'f \Rightarrow 'f \Rightarrow 'f
— Function update, map update, list update...
            :: 'f \Rightarrow 'k \Rightarrow 'v \Rightarrow 'f
— Domain of maps, lists...
udom
             :: 'f \Rightarrow 'a \ set
— Range of maps, lists...
            :: 'f \Rightarrow 'b \ set
uran
— Domain restriction
udomres :: 'a set \Rightarrow 'f \Rightarrow 'f
— Range restriction
uranres :: 'f \Rightarrow 'b \ set \Rightarrow 'f
   Collection cardinality
ucard
            :: 'f \Rightarrow nat
— Collection summation
usums
             :: 'f \Rightarrow 'a
   Construct a collection from a list of entries
uentries :: 'k \ set \Rightarrow ('k \Rightarrow 'v) \Rightarrow 'f
```

We need a function corresponding to function application in order to overload.

```
definition fun-apply :: ('a \Rightarrow 'b) \Rightarrow ('a \Rightarrow 'b)
where fun-apply f x = f x
declare fun-apply-def [simp]
definition ffun-entries :: 'k \ set \Rightarrow ('k \Rightarrow 'v) \Rightarrow ('k, \ 'v) \ ffun where ffun-entries d \ f = graph-ffun \ \{(k, f \ k) \mid k. \ k \in d\}
```

We then set up the overloading for a number of useful constructs for various collections.

```
adhoc-overloading
